DAIRYING VERSUS RAISING BABY BEEF ON EYRE'S PENINSULA.—The following paper was contributed by Mr. J. H. Vigar:—"Owing to its geographical position Eyre's Peninsula is somewhat at a disadvantage from a dairying point of view. Port Lincoln—the only outlet where creameries are operating—is at the extreme end of the rail and road transport service. Apart from the closer districts the greater portion of the agricultural areas is outside the 30-mile radius from Port Lincoln, and transit charges make the butterfat returns so low that it does not pay the producer. Taking the South Australian butterfat average at 150lbs., at the present time butterfat returns for Eyre's Peninsula would not exceed 6d. a pound clear, therefore the return per cow would be £3 15s., and no dairying can be made to made on that return per cow. *Baby Beef.*—I have had experience with this means of deriving returns from my dairy cows. I have never sold baby beef under 18 months old for less than £6 per head on trucks, and have received as high as £9 for a 10 months old heifer. The former value was realised when prices were at about to-day's level; the latter about five years ago, when prices for butter and beef exceeded those of to-day. The baby beef I have raised has been the Jersey cross, and they would not be better in quality or weight than the average beast on the Peninsula. The experience I have had of both methods convinces me that the raising of baby beef pays best, and the work is not the same tie and drudgery. Where only a few cows are kept—say, two to four—a certain amount of the milk is needed for domestic purposes. It is an advantage to control the calves by having a securely fenced paddock adjacent to the cowyard and seldom allowing the calves to run with the cows. The cows are quieter, always come home to be milked night and morning, and do not develop sore teats as is sometimes the case when calves run with the cows. It is then an easy matter to secure sufficient milk for the house. I have a chain and a strap attached to the calf's neck, and hook the calf back to be able to get the richest of the milk. Some members may raise the question of pig and poddy values, but they can be cut right out of the reckoning. Under my management a couple of pigs may be kept, and with most small dairies, after the calves are reared with skim milk, no more than two or three pigs can be kept through to baconers. The poddy may be worth 30s. at 12 months old but even this does not equal up the returns, to say nothing of the extra work involved. To secure the same value for the poddy as from the baby beef off the mother the poddy would have to be fed for an extra 18 months or two years, and probably many of these beasts are sold as stores by the men who bred them, and only realise half their value. If conditions are such that the breeder decides to hold the baby beef beast to exceed two years it will be found that that beast will keep its condition and will, in most cases be easy to turn off in prime condition owing to its strong constitution and better start in life." (Secretary, A. Myers.)

YADNARIE (Average annual rainfall, 14.09in.).

August 15th.—Attendance, 9.

RABBIT DESTRUCTION.—Mr. M. Way, who read a paper on this subject, spoke in favor of poisoning as the best method of keeping the pest under control. He suggested the following procedure:—For the first few days distribute wheat that has been soaked in water, but not poisoned, along the fences and around the burrows and warrens. When it is noticed that the rabbits are cleaning up the grain, poisoned wheat—by soaking it in water and then sprinkling brown sugar and strychnine over it—should be substituted. Mr. Way used as much strychnine as would twice cover the small blade of a pocket knife to treat 1gall. of wheat, and had found this a most effective method. Mr. W. Brown condemned the use of poisoned grain, because it was responsible for the destruction of many valuable native birds. (Secretary, E. Spriggs.)

August 22nd.—Attendance, 12.

GRAFTING VINES.—In the course of an address on this subject Mr. F. R. Arndt (District Horticultural Instructor) said that little had been done to investigate the grafting of European vines on European stocks, though the disastrous visitation of phylloxera in France and later in Victoria caused great investigations into the best stock of resisting quality from America for different varieties of European vines. However, some work had been done on the River, and it was definitely known that sultanas and currants did well on Doradillo stock, and bore crops of good quality and quantity up to at least 10 years. Also it had been found that Shiraz was not to be recommended on a Doradillo stock. Currants as a stock for sultanas gave good but small fruit. In the actual grafting it was advisable to have the cuttings for the scions prepared in ordinary lengths and buried in moist but not wet soil before they commenced to burst their caps on the vines. The scions should be a little drier than the stock, and it was not advisable to graft while a great rush of sap was coming from the stock. If the vine used as a stock was cut down just below the wire before grafting day it would allow the excess sap to drain away. The sap must be rising, but not in flood. A split was made in the top of the sawn-off stump, which should be just below ground level. Then the scion containing at least two buds was pared wedge-shaped and inserted in the split, one on each side, great care being taken that the cambian layer beneath the barks of both stock and scion were placed adjacent—actually touching—each other. The more that was touching and the firmer the wedge in the stock the more chance there was of a “take.” One point to remember was that the scion should be pared slightly thicker on the side intended to touch the bark of the stock. After that had been done damp, loose earth should be heaped up all over the stock and scions to keep the latter alive and green. It was advisable to keep the heap over the stock all the first season to enable the scions to make a strong growth of their own roots. (Secretary, R. Telfer.)

MOORLANDS (Average annual rainfall, 14.76in.)

August 16th.—Attendance, 10.

WORKING A LIMESTONE BLOCK.—Paper read by Mr. J. Herbert:—“A limestone farm is one of the hardest to work, especially where there is a wide variation of the types of soil. The best method—from the start of clearing—is to give the ground three crops—two of wheat and one of oats. With good burns this should practically kill all shoots. Any ground too rough for wheat should be ploughed dry occasionally, to loosen the soil. It will also encourage the growth of grass. A dressing of super when ploughing will also help in this direction. Fallowing is suggested for the wheat-growing land, but care must be exercised, otherwise the soil will drift on the sandy loam and leave bare rock. For this class of soil the best method is to plough in July and leave in the rough state. Later in the season turn sheep on this ground to keep weeds from seeding

which have been missed by the plough. Another method is to fallow early, then cultivate and drill in oats at the same time to check drift. This crop can be fed down late in spring. Work with the first rain after harvest and the land will be nearly as good as bare fallow. Where sheep are not available the best way is to plough the ground to be cropped dry to bury all weed seeds and give a good germination with the first rains. This will obviate a lot of working later in the seeding. The grey and red ground should be fallowed in July and worked over late in September or early in October with a cultivator, using wide shares to leave ridges that will help to check drift. Another essential practice in this district is to get the crops in early; finish seeding by the first week in June. Crops sown after that date rarely yield as good as those sown earlier. Keep the stones picked; if this is not done the ground is hard to work, is rough on man, horse, and implements. In the early stages of development, cropping with oats cannot be overdone. Portion of the oats can always be sold, and the rest fed to stock." (Secretary, R. Wilmshurst.)

RAMCO.

July 31.—Attendance, 8.

IRRIGATION.—The following extracts are taken from an address delivered by Mr. A. Seary, who considered that the question of water used and seepage on blocks was one needing consideration. He had taken a block on which seepage was bad with the water table close to the surface. He put down trial holes in an apricot block, which showed no roots of any value below 3ft., consequently the quantity of water needed was enough to fill that 3ft. Further quantities would be of little use. The water table was rising, and it was necessary to reduce it. In winter the table fell a little, and in summer the land was irrigated and filled up the loss and added an inch or two. In his opinion if they applied only sufficient to fill up the 3ft. it would be the end of their troubles. Different soils required different amounts of water to soak it. He had experimented, and found that with an average stream using 30 to 36 2in. outlets he could water an acre in 1½ hours. That was for average soil. For sultanas with a heavy crop with peas ploughed more water would be necessary. How to spread the water between rows was a problem. Some suggested the alteration of the layout of the block, but that was expensive. He had rows of currants 9 chains long with a very shallow water level. At the first irrigation he put a very deep furrow and banked between the rows and turned two full outlets in the one furrow, and broke in between the trellis. At the second irrigation one furrow watered them. At the third irrigation he could use four furrows, and he had got rid of underground water. On the centre of the block he had a drain 4ft. 6in. deep. Last season the drain remained dry, therefore he had no water going down, and had lowered the level. A lucerne block, where water had been turned in at night and left until morning, had a very high water level. He kept the water off one year, and fenced and turned horses in. He put down holes, and found that the water had gone down to 8ft. from the surface. Sultanas around the lucerne plot improved 99 per cent. by weight of dried fruit, because there was no water lying around. Another patch had 2 chains of stony ground, then a type of soil that would not take water—the first part would wash but the other run over. With a quick slope of 18in. to the chain for the first irrigation he used two furrows, and at every trellis post and once between he banked across and turned in the water, making a pool, say, every 6ft. It was costly, but next time the water had soaked away. Now he could water normally. As a general principle in irrigating as many furrows as possible should be used. At the beginning of the season it was advisable to get underneath the vines, because later on that could not be done. To put that plan into practice it was necessary to keep at it night and day. He did the night watering and another man the day work. The object was to get the water over the waterlogged patches, and then let them dry a little. It took a lot of work to get the ground into its present condition, but he was getting some result. A good discussion followed. Mr. F. Lewis said the speaker had done a tremendous amount of work. At Ramco the problem was different, for they had a steep slope and very deep sandy soil. He had one patch where 2in. outlets took four days to get through, yet that patch was first to show need of water. (Secretary, J. Odgers.)

INSECT AND FUNGUS PESTS AND THEIR CONTROL.

(Notes from an Address delivered by E. Leishman, District Horticultural Instructor, at the August meeting of the Murray Bridge Branch of the Agricultural Bureau.)

The most common diseases of plants are those caused by the depredations of insects and mites, or by minute parasitic plants, called fungi. To combat satisfactorily any fungus disease or insect pest, it is necessary to have some knowledge of its life history. Fungus diseases are divided into:—(1) Those that are external, and are known as

Ectophytic fungi, such as Powdery Mildew. (2) Fungi which live in the internal structures of the plants, which are called *Endophytic*, such as Peach Leaf Curl, Shothole of Apricot, Fusicladium, &c.

External fungi, such as Oidium or Powdery Mildew of the grape vine, can be treated after infection. This fungus sends its root-like growths through the stomatas of the leaves, tender shoots and developing fruits to the internal cells, and drains upon the food supply of the plant. The control measure adopted for this disease is to dust the vines with flowers of sulphur. The heat of the sun causes some of the sulphur to vaporise, and the fumes passing through the vines destroy the fungus.

Internal Fungi are kept in check by the same spray washes, with the exception of Anthracnose of the vine, for which winter treatment with acid-iron solution is essential. Applications of fungicides for the internal fungus are purely preventive, for once the disease enters the tissues of the plant it cannot be destroyed without destroying the affected part. This being the case, one must study the conditions and times under which the spores are most likely to germinate, and coat the plant with a fungicide before the spores germinate. The chief fungus diseases which concern growers on the River Murray are Peach Curl Leaf, Shothole of Apricot and Almond, and Anthracnose of the Vine. Peach Leaf Curl Fungus can be controlled by spraying with copper mixtures such as Bordeaux and Burgundy, when the pink of the blossoms is just showing through the bud scales. Spraying in autumn just before the leaves drop is a good control for Shothole, and spraying again at the pink stage in spring successfully checks this disease. For Black Spot on apples and pears, a fungicide such as Bordeaux or Burgundy mixture, and lime sulphur should be sprayed at the pink stage and after flowering. Autumn spraying has proved successful. Anthracnose, or Black Spot of the Vine, is controlled by swabbing the vines in mid-winter, with a mixture made by pouring 3lbs. to 5lbs. of sulphuric acid over 35lbs. to 50lbs. of iron sulphate, then dissolving this in 11galls. of boiling water. Spraying with a 10 per cent. solution of sulphuric acid is often used instead of swabbing. Spraying with Bordeaux mixture when the shoots are 4in. or 5in. long will check the disease.

Insect Pests.

Insect pests are divided into two sections:—(1) Mandibulate, or chewing insects; (2) *Haushtile*, or sucking insects. Chewing insects—for example, codlin moth, curculio beetle, cut-worms, &c.—are controlled by coating their food with poison—usually an arsenical compound—which kills the pest. Sucking insects, for example, scale insects, aphides, mites, &c., are controlled by spraying the insect itself with liquids, such as nicotine, oil sprays, &c., which burn the tender skin of the insects or suffocate by poisonous gasses, such as hydrocyanic acid gas, carbon di-sulphide, &c. The Codlin Moth has quite recently spread to the River. The eggs are laid on the plant, and when they hatch the grubs progress towards the centre of the plant. Spraying should therefore be done when the petals have fallen, and before the calyx of the apple closes up. The hatching period depends on weather conditions. Four or five sprays of arsenate of lead are necessary during the growing period. Some experimental work has been carried out in the Hills on control by means of traps, which take the form of molasses in water hung in a vessel in the tree. Bandages have also been used, and the latest kind are made of corrugated cardboard saturated with poison. Unfortunately the poison loses a good deal of its power towards the end of the season. Curculio Beetles should be treated with arsenate of lead, 1/10.

Aphis.—For Black Aphis the controlling principle is to spray with a contact spray of nicotine on alternate days, with 3 sprays at least. This pest makes its first appearance in spring, when the small leaves are coming out. The green aphid is larger than the black, and lays its eggs throughout the winter. Tar distillate spray has been tried at Mypolonga, with very good results.

Scale.—Black and Brown Scale of the orange are not regarded as serious, and are fairly easy to control. Thin out the trees and spray with white oil or kerosene emulsion in October or February. Red Scale is the worst scale on citrus trees, and is a most prolific breeder, producing living young. The scale really feeds on the most succulent part of the tree, and is seldom found on the harder growths. The most efficient control is by fumigating with hydrocyanic acid gas, by enclosing the tree in an air-proof tent. This is the most practical method, although white oil will give a 70 per cent. control. Fumigating gives a 98 per cent. kill, and gives freedom for about 3 years if all the orchard has been heated.

Cut Worms.—Arsenate of lead is a control, although baits consisting of Paris green mixed with bran are very satisfactory.

Numerous questions were asked *re* control of various pests. Biological control for Woolly Aphis and Red Scale were described.

BLACKWOOD (Average annual rainfall, 27in. to 29in.).

August 14th.—Attendance, 21.

MANURING FRUIT TREES.—The following notes are taken from an address delivered by Mr. W. J. Spafford (Deputy Director of Agriculture):—"General reviews in America show that fruit trees give little response to commercial fertilisers. Modern research is now aiming at finding out the effects of a deficiency of foods rather than the effect of a surplus of foods. The main factor is the health of the trees, and often cultivation will do what manures cannot, and it is to be remembered that nitrogen can be supplied by correct cultivation just as well as by manures. Plant food deficiencies—when they occur—are usually nitrogen, phosphoric acid, and/or potash. The only plant food that gives results with any degree of certainty is nitrogen, which has the effect of encouraging healthy growth. In the Government Orchard nitrogen makes the trees grow better, although crops may not show much increase. These trees, however, will probably carry good crops longer than trees not receiving nitrogenous manures. In our climate, soil bacteria collect large amounts of nitrogen from the air. It has been found at the Waite Research Institute that the bacteria in fallowed land collect nitrogen from the air at the rate of the equivalent of a dressing of 600lbs. of sulphate of ammonia per acre per year, so it can be seen that good cultivation can help a lot by keeping the soil in a condition which will enable the bacteria to flourish. Potash deficiency is shown in Europe and Great Britain by leaf scorch, and is corrected readily by applications of potassic fertilisers. This condition is not found here, but this may be due to climatic conditions. Sunshine enables plants to absorb potash, but cold and cloudy climates tend to retard absorption. In this district applications of potash have no beneficial effects. The addition of sulphate of iron seems to keep the trees healthy and tends to make them crop evenly. Phosphoric acid is not plentiful in Australian soils, but trees show no special need for more, and the addition of phosphoric acid gives no economic increases in most cases. Soil texture is very important. Bacterial life is enormous in the surface layers of soils, and their full activity depends largely on soil texture. Wet and sticky soils, as well as dry and powdery, are bad habitats for bacteria. Some bacteria collect nitrogen from the air, and in doing it liberate plant foods from the soil particles. Sourness in our hills soils is not very detrimental to the fruits grown, and so an application of gypsum to the soil might be more profitable than an application of lime, as it improves the texture, although slightly increasing the acidity of the soils. Humus is to be imagined as a sort of colloidal jelly which, surrounds soil particles and holds plant foods. Extra humus is needed in our hills, as it will improve soil texture and bacterial action. In this respect gypsum might give more economic results than green manuring in some soils, by improving soil texture and thus increasing bacterial activity. If trees are not healthy, the first thing to do is to try to improve them by better methods of cultivation. If this does not succeed, then apply nitrogen, the cheapest form of which is sulphate of ammonia. Nitrate of soda is slightly quicker in action. The application should be between 3lbs. and 7lbs. per tree. As nitrogenous manures are very soluble, they quickly reach root level. Oranges require nitrogen, especially in sandy soils. If green manures are used to increase the nitrogen content of the soil, it is necessary to apply phosphoric acid to get a good growth of greenstuff.

"If gypsum is used to improve soil texture it should be applied at the rate of 1 ton per acre. Lack of growth in natural weeds in an orchard is most likely due to compacted soil and continued working, and not to lack of soil fertility. It may be necessary to green manure to keep organic matter in the soil for the bacterial activity. Gypsum may lighten the soil for some years, but occasionally green manuring must be practised to add organic matter. It is essential to have green crops early, and peas and rye are about the only quick growers that are suitable and which can be depended upon to do well. Rye should be planted at the rate of 40lbs. per acre. It is better to use more than less, because a heavy seeding gives rapid and luxuriant growth. All annuals planted should be drilled in with super to give them a good start, because they receive most of the phosphoric acid while very young." (Secretary, H. Goldsack.)

CHERRY GARDENS (Average annual rainfall, 35.03in.).

Attendance, 16.

An afternoon was spent with other residents at a Working Bee in the local Soldiers' Memorial Park, digging and cleaning around ornamental trees, shrubs, &c. Afternoon tea was provided by the ladies. The evening meeting was held at Mr. H. Jacob's residence, when the ordinary Bureau business was carried out. Reports of Congress were received, and items of local interest discussed. (Secretary, A. Stone.)

LANGHORNE'S CREEK (Average annual rainfall, 14.76in.).

August 30th.—Attendance, 7.

Mr. J. B. Natt addressed the meeting on "Breeding up a dairy herd." The speaker outlined how a few years ago he began with a few cheap cows of no particular breed, mostly bought in the sale ring, and by continuing to use the Shorthorn bull had at the present time quite a good herd of grade Shorthorns. He had obtained high prices for heifers and bred some high producers, one or two outstanding individuals reaching as high as 8galls. of milk per day and 17lbs. of butter per week. Mr. Natt preferred shelter rather than rugging and that heifers should not calve until 2½ to 3 years of age. A good discussion followed. (Secretary, P. Nurse.)

Cow Judging Competition, Mypolonga Agricultural Bureau.

LENSWOOD AND FOREST RANGE (Annual average rainfall, 35in. to 36in.).

July 27th.—Attendance, 15.

FORESTRY.—Mr. H. N. Wicks, in the course of an address, stressed the value of trees to mankind. How that they renewed the oxygen supply so necessary for life, made living conditions cooler, and promoted rain. They also kept conditions warmer in winter and, most important, provided timber for the many uses it was put to to-day. Pines were most useful trees, the timber of which was utilised for many industries. America was in a serious position in regard to timber as her consumption was far in excess of her growth. He stated that *Pinus* made better flooring than the imported Baltic, having less knots. Also sleepers for railways treated with cresol outlasted jarrah and red gum. Newspapers consumed annually 15½ million tons of timber. For planting pines the ground should be fairly clear, and the trees planted from 6ft., 8ft., 10ft., or 12ft. apart, depending on the nature of the ground. They should receive attention the first year; a little drop of water sometimes to help them through the summer. The trees grew up until they reached the mature height, and would then develop the trunk. It was highly important to have good firebreaks as a precaution against fires. At the conclusion of his address Mr. Wicks exhibited specimens of turned woodwork made from various woods of South Australia.

Mr. Max Vickers then gave a talk on "Flowers and Ornamental Shrubs." He exhibited many specimens of ericas, grevilleas, fuchsias, wax-plants, acacias, gums, wattles, conifers, and firs, describing each and giving their names. Supper was served by ladies at conclusion of meeting. (Secretary, B. Lawrance.)

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

August 24th.—Attendance, 7.

CROP ROTATION.—Mr. B. Wheaton presented the following paper:—"No crop can be grown successfully and economically on the same ground year after year indefinitely. The land sooner or later becomes infested with weeds and disease, or deficient in plant foods. In every district a system of working the land must be developed if agriculture is to be permanent. This system may be a succession of different crops with intervals of rest running over a period of years, or one crop, alternating with a period of fallow or grazing. The state of agricultural development of a country or district is largely indicated by the complexity of its standard rotation. Thus, in the Prairie country a few years ago there was no attempt at a rotation system at all, and the north-west of New South Wales the same practice still applies, while in Great Britain and Europe numerous rotations covering from four to nine years are rigorously observed in different types of soil. In the lower north of South Australia and Yorke Peninsula rotations of three, four, and even five years are in force. Reasons for and objects and advantages of a rotation: Different crops require plant foods in variable quantities and obtain them from different depths. Thus, a variety of crops utilises the sole resources thoroughly; pasture grasses and barley are shallow, while wheat is deep rooted. Each crop has more or less specific diseases which infest the soil if the same crop is grown repeatedly. One way of combating these diseases is to keep the host plant from the soil for a period of years, of which a typical example is take-all and flag smut in wheat, which can be starved out by growing oats, because they are not attacked by these diseases. Each crop is infested, more or less, by a particular weed or class of weeds and the land can be more thoroughly cleaned by growing crops which occupy the land at different seasons of the year. In growing cereals it is essential to have a legume in the rotation, and this can be supplied by burr and other natural clovers, which add considerably to the nitrogen content of the soil. In designing a rotation, no ground should carry the same crop twice in succession, and a leguminous crop should be included every three or four years. In order to maintain the humus supply, one crop in a rotation and all stubble should be grazed off, except in so far as wheat stubbles are burnt, to kill weed seeds and disease spores, and clean the ground ready for early ploughing or cultivating, which should be done immediately after burning to retain the ash. A rotation of fallow, wheat, oats, or barley and pasture has proved suitable for the district. Fallow conserves moisture and makes nitrogen available for the wheat crop, as well as affording an opportunity to free the ground from weeds. If there is suitable rain in summer and the fallow is well worked down, a crop of turnips may be grown if the soil is not too heavy. In addition to providing good sheep feed and saving the natural pastures just when they are beginning to grow, a considerable amount of organic matter is added to the soil. Such a crop does not affect the wheat yield to any appreciable extent, providing it is fed off in time to get the ground in good order for the cereal. Wheat stubble should be burnt off as soon as the sheep have finished grazing on it and the land prepared for barley or oats. The second crop should be sown with a heavy dressing of super, which will ensure a prolific growth of clovers and subsequent heavy grazing in the final course of the rotation. Some of the advantages of this system are that seeding will allow oats, wheat, and barley to be sown at the best time with a substantial addition of organic matter to the soil. The changing of crops is the most effective method of preventing disease, work is more evenly distributed throughout the year, and fertility of the soil is maintained. The inclusion of pease in a rotation—either as a forage crop or for grain—will greatly benefit the soil, and a rotation of fallow, wheat, pease, wheat or oats, grazing, has been used to advantage in parts of the lower north, and could no doubt be used to advantage on the island." (Secretary, J. Wood.)

WOMEN'S BRANCHES.

BELALIE (Average annual rainfall, 17.71in.).

September 5th.—Attendance, 21.

A paper, "Making the Best Use of the Sheep," was read by Mrs. F. Cummings. The following were read as answers to questions taken from "Question Box":—"A remedy for sore teats in cows?" *Answer*: Fresh, unsalted butter mixed with sulphur, or vaseline mixed with boracic and lard. A little lard mixed with boracic powder rubbed on after milking will keep the teats from cracking during cold, frosty weather. "How to remove oil spot from a light marocain frock?" *Answer*: Make a paste of benzine and block magnesia, place over the oil spot, and allow it to become quite dry, then brush off. Repeat if necessary. "How to make a good floor polish?" *Answer*: 1 pint turpentine, 2 pints water, $\frac{1}{2}$ lb. beeswax, 1½ ozs bicarbonate of potash. Boil water, potash, and wax until creamy. Take off fire and add turpentine. "To remove inkstains from linoleum?" *Answer*: Oxalic acid rubbed on with a cloth is the quickest and easiest way of removing inkstains from linoleum without injuring the surface. The following is a list of authors sent in reply to a request for a list of "Good Books":—*More Serious Literature* (authors)—J. Galsworthy, Warwick Deeping, Stephen McKenna, and Compton McKenzie. *Lighter Reading* (authors)—D. K. Broster, Guy Fletcher, Georgette Heyer, Peter Kyne, Mary Roberts Reinhardt. *Humorous Works* (authors)—Jacobs, Ben Travers, E. J. Rath. *Stories of Cattle Ranches and Mining Camps* (authors)—Jackson Gregory, A. M. Bower, Zane Grey, William Macleod Raine, Henry Oyen. *Detective Stories* (authors)—Edgar Wallace, J. T. Fletcher, Frank Packard, J. Austin Freeman, T. T. Van Dine. *Adventure* (authors)—P. C. Wren, Dornford Yates, Louis Tracy. (Secretary, Mrs. A. Cummings.)

CLARE (Average annual rainfall, 24.53in.).

September 5th.—Attendance, 12.

CHICKEN AND TURKEY RAISING.—Mrs. A. Blight contributed the following paper:—"This is a very interesting and profitable hobby. For incubator chickens hatching for heavy breeds extends from June to September. The light breeds are later, on account of the cold weather. For successful hatching of chickens, selected stock, a good incubator, and plenty of patience are essential. See that the incubator is perfectly clean, properly regulated, and set in a well-ventilated room free from draughts. An incubator of 60-egg capacity is large enough for a beginner; later on a larger one can be purchased. Choose the best eggs and mark each side with colored pencil, so that there will be no trouble when turning begins. Set the incubator at 103° first week, 104° second week, 105° third week. Start to turn the eggs on the fifth day and test eggs on the seventh day. In testing a small figure, similar to a spider, will be seen in the centre of the egg. This is the embryo, and any egg that does not show this is infertile and must be removed. The third week fill up trays with water and sprinkle eggs night and morning. For this a barber's spray is recommended. On the twentieth day the eggs should start pipping. Do not open drawer until after the hatch is over. When the chickens have dried, remove to the top of the incubator. Do not feed for 24 hours. The feeding of chickens is very important. The first meal should be of sand; later a little warm milk can be given, also No. 1 chick food. Bread is not good for incubator chicks. As they get older, lettuce and raw meats cut very finely, bran mash and chick food No. 2 are recommended. Do not give chickens water; they thrive better on milk. Care must be taken that they do not catch a chill. A home-made brooder is quite satisfactory for small hatchings. Keep the chickens in coops and chick pens until they are big enough to mix with fowls in the yard. *Feeding Turkeys*.—Keep the mother and young turkeys in a coop, cover up at night to prevent chills, and feed as follow:—Hard-boiled eggs with plenty of pepper for the morning meal, onions, lettuce, and scraps of meat chopped finely at midday, and eggs and bran mash at night. Give very little water; I do not give bread." (Secretary, Mrs. McKendrick.)

COONAWARRA.

September 20th.—Attendance, 21.

SWEET MAKING.—Miss D. Stafford read the following paper:—"For cooking, an aluminium or enamel saucepan to hold about two quarts is required. Have a stove that gives a good even heat. Great care must be exercised with the heat in order not to scorch the syrup before the proper degree of boiling has been registered. Sugar boiling is an important item in sweet making; especially does the success of fondants, nougats, caramels, &c., depend upon it. For cooling syrups, a large china meat plate, slightly dampened, is used. It should be perfectly smooth, otherwise it is

likely to grain the syrup sugar. Be careful not to over-color or over-flavor the sweets. See all nuts are quite good; a rancid nut will spoil a whole batch of toffee or fondant, because sugar absorbs flavors rapidly; cream of tar is used with sugar to prevent granulation. Lemon juice is also used for the same purpose. If too much is used, the fondant becomes soft; if not enough it is hard and sugary. *Fondant*.—Place 1½ lbs. of sugar, scant ½ teaspoon cream of tartar, and about ½ pint of water in a perfectly clean saucepan. Set on stove and stir with a hardwood paddle until sugar is thoroughly dissolved. When the batch comes to the boil, skim off all foreign substance carefully, place a lid over the saucepan, and allow to boil 2 or 3 minutes. Then remove the cover, wash down sides of the saucepan thoroughly and boil for 15-20 minutes. Remove from fire and pour syrup on dampened platter and allow it to become lukewarm, then it is ready for the creaming process. With a wooden paddle stir and work the syrup vigorously, turning it over at each stroke to fold the outside edges into the batch. Almost immediately the batch will appear cloudy, and by continuing to stir and beat it, it will finally set into a firm lump of pure white cream, which can be kneaded with the hands. Cover it with a damp cloth. Keep in a cool dry place. Cream centres made from fondant a few days old will be superior to those made from fresh fondant because it has time to mellow. To test without thermometer: Drop a little of the syrup from time to time in a little cold water, and when it forms a firm ball between the fingers it is cooked. *Snowballs* (Misses E. Skinner and F. Jackson).—Soak 1oz. gelatine in 1½ gills water 20 minutes; boil together 1lb. sugar, 1 gill water, boil until sugar is dissolved. Add gelatine and water, boil 10 minutes longer; turn mixture into large bowl. Beat until cool and stiff. Pour mixture into eggcups, marmite jars, small glasses, &c., to set. Turn out, dip into chocolate coating, then roll in cocoanut. *Chocolate Squares* (Mrs. Jackson).—1 pint sugar, ½ cup butter, ½ cup water, 1 cup grated chocolate, 1 tablespoon vinegar. Put all on to boil, stirring all the time. When it thickens pour into buttered dish. Cut into squares. *Clear Toffee* (Mrs. W. L. Redman).—1 cup sugar, ½ cup water, butter size of egg, pinch cream of tartar; boil (without stirring) until it sets when tested in water. *Creamy Toffee* (Miss E. Skinner).—1 cup each cream and sugar, flavoring; boil until sets—about 1 hour. *Caramel* (Mrs. W. L. Redman).—1 large cup sugar, 1 level tablespoon flour mixed well together; add butter size of egg, 2 tablespoons golden syrup or treacle, and ½ cup milk. Stir all the time—about ½ hour. Test in water. Pour on to buttered dish, cut in squares. Chocolate may be added if desired. (Secretary, Mrs. F. Skinner.)

November 16th.—Attendance, 28.

CHRISTMAS GIFTS.—Miss M. Reschke exhibited and explained the making of many gifts suitable for Christmas. These included:—*Pin Cushion*.—Take an empty Alpine Snow jar, line with material, fill with sawdust, sew a frill of ribbon and lace around top, and finish off with a kewpie. *Tie Holder*.—Paint three large cotton reels, and thread on ¾yd. ribbon, making a bow at top. *Work Box*.—Secure a wooden box, hinge the lid, stick a pattern of halved walnut shells around sides and on lid, paint the box and varnish the walnuts, line the inside—the top of this may be padded. *Picture Frame*.—A wooden frame, e.g., three-ply, with a pattern of gum nuts and halved walnut shells stuck on, and all painted. *Shoe Trees*.—Buy the plain trees and 2yds. of two different width ribbons, gather, and put on the shoe trees; paint or varnish the ends. *Handkerchiefs*.—Buy plain handkerchiefs, crochet around, and a spray may be worked in one corner. To make crocheting easier, unthread the machine, and sew around edge of handkerchiefs—this ensures even stitches as well as making it easier to push hook through. *Safety pin holder*; powder puff in crocheted bag; shoe bag for travelling (made from cretonne); knitted socks for father; milk jug covers; crocheted sauce bottle covers; teapot and egg cosies (knitted in wool); duchess set (pen painted); worked tea towels; doyleys (crocheted and worked). Gifts exhibited by other members were:—Mrs. J. Skinner: Fluffy woollen ball (covered tennis ball in colored wools; novel table mat made from different colored wools; a doll made from old stocking and dressed; peg apron; and milk jug covers. Mrs. Hoffmann: A cord to place around neck when sewing with a bag at intervals to hold the thimble, a pin cushion, needle holder, and a scissors holder. Mrs. L. Redman: Mending Bag.—Cretonne with lining and pockets to hold wool, scissors, needles, &c. Mrs. Jackson: Vases. Enamel black a pickle jar or bottle; stick pieces of paper all over—the one exhibited had pictures off jam tin covers cut out and pasted on—they need not be in a pattern; varnish with clear varnish over all. Mrs. O. Skinner: Set of Covers.—Out white net (double) into four different-sized squares, crotchet edges or turn hem and herringbone, thread about 1doz. beads on thread, and secure at each corner; handy in summer time. Miss C. Skinner: Calendars.—Cut black velvet into shapes, e.g., a cat or Dutch windmill; paste on cardboard; paint sky and wall for cat, or scenery for windmill; paste on back loop of ribbon for hanging, and another at bottom to paste calendar on; cover back with brown paper.

CAKES AND BISCUITS.—*Light Pound Cake* (Mrs. Modistach).—½lb. each butter, sugar, sultanas, currants; ½lb. mixed peel; 7 eggs; 1 tablespoon brandy; 1 dessertspoon treacle; ½lb. plain flour; ½lb. S.R. flour. *Christmas Biscuits* (Mrs. Hinton).—6 eggs, ½ pint warm water, ½lb. butter, 1oz. rock ammonia, 2 tablespoons peppermint, 2lbs. sugar, 3lbs. plain flour. Beat butter and sugar; add well-beaten eggs; add flour gradually, and ammonia dissolved in water; keep few weeks before using.

CHRISTMAS COOKING.—Paper read by Mrs. Reschke: "I usually make Christmas cakes and puddings a month or six weeks beforehand so that they have the full flavor of the fruit, &c., that have been mixed in them. Clean the currants, raisins, and sultanas a few days before making the cakes and puddings so that they are then thoroughly dry—wet fruit often sinks to the bottom of the cake. Have fairly solid tins in which to bake the cake. Aluminium saucepans the right size are excellent; they are much thicker than tin, and do not burn. I always use tin cake dishes. Grease them well, and line with clean brown paper. I generally use about four thicknesses, or 2ozs. of brown paper and 2ozs. of white. Christmas cakes need from 3½ to 4 hours' baking. Puddings should also be made a month or so before Christmas. The fruit must be washed, cleaned, and dried beforehand. The length of time the pudding needs to boil depends on the size. Where there is a large family, and a large pudding is required, it will take 4 hours. When sufficiently boiled take straight from the saucepan and hang in a cool, airy place until required for use. Biscuits and sweetmeats are also very nice dainties to make up a week or two before Christmas. Plainer cakes can also be made, and are most useful; friends often come in at Christmas, and plenty of cakes for afternoon teas and suppers, as well as the Christmas cake, are always handy. *Christmas Dinner.*—If a ham is to be used cook it the day before. If it has been cured some time and it is a little dry soak it in clean water overnight, and then boil next day, the length of time being according to the size of the ham. If rather salty allow it to come slowly to the boil and boil steadily for half an hour, and then pour off the water and replace at once with boiling water from the kettle. When boiled sufficiently remove the saucepan or boiler from the fire, and allow the ham to remain in the water until nearly cool. Then remove from the water, peel off the rind, sprinkle with fine bread crumbs, and place in the oven for a few moments to brown them. Prepare the poultry for Christmas dinner the day before, and hang in a cool place overnight. Make a good stuffing with fine bread crumbs, salt, pepper, and mixed herbs, and stuff the bird. Place it in the roaster, sprinkle with salt and pepper, and enough good dripping, and a little water, and roast according to the size of the bird. If a large turkey roast steadily for 4 hours, most of the time with the lid on roaster. Take off the lid to allow it to brown before taking it up. A goose usually takes 3 hours, ducks 2½ hours, and a fowl about the same time. Make a good brown gravy, and serve hot. For dessert serve the pudding hot with sauce. For Christmas tea cold poultry over from dinner, cold ham, and salads. Lettuce salads and jellied beetroot are very nice, or tomatoes and cucumbers. For dessert, jellied fruits and cream, sweetmeats, Christmas cakes, biscuits, and fresh fruits. Cool drinks are also much favored by most people at Christmas, and are very refreshing on a hot day, and some good home-made ones can be made; they are inexpensive and wholesome. *Christmas Cake.*—½lb. each butter and brown sugar; ¼lbs. flour; ½ teaspoon salt; 1lb. each currants, sultanas, seeded raisins; 1 dessertspoon spice; ½ grated nutmeg; 2 teaspoons baking powder; ½lb. each candied peel, almonds, crystallised cherries, figs; 8 eggs; 1 glass brandy; 1 glass cinnamon. Method:—Prepare the cake tins as already described; have fruit ready; chop almonds; wash and dry cherries; sift flour, spices, and baking powder; cream butter and sugar well until sugar is thoroughly dissolved; beat eggs well; add them gradually to the butter and sugar; then add flour and some fruits, more flour and fruit, until they are all used up; lastly the brandy. Do not have it too moist. Bake in moderate oven 4 hours. A few days before Christmas ice and decorate with royal icing. *Plum Pudding.*—½lb. each butter, brown sugar, currants, raisins or dates, sultanas; ½lb. mixed peel; 6ozs. each bread crumbs and flour; little salt; ½ teaspoon mixed spice; 4 eggs; a little brandy. Boil 4 or 5 hours. *Mince-meat for Mince Pies and Tarts.*—½lb. each raisins, sultanas, currants; ¼lbs. apples; 1oz. mixed spice; ½lb. candied peel; ½lb. brown sugar; 1 cup wine or 4 tablespoons brandy; 1 teaspoon nutmeg; ½lb. good beef suet; 1 teaspoon cinnamon. Put all through a mincer, and pack tightly in jars, and tie down. When wanted for pies or tarts use short crust. *Christmas Plum Pudding.*—3 dessertspoons gelatine; 3 cups milk; 1½ squares chocolate or 3 tablespoons cocoa; ½ teaspoon vanilla; ½lb. each chopped nuts and lemon peel; ½ cup each raisins, dates or figs, currants; little preserved ginger; ½ cup sugar; little salt. Method:—Place milk and chocolate (or cocoa) in saucepan; bring to boiling point; add all ingredients except gelatine, and boil 5 minutes. Let cool; dissolve gelatine in ½ cup hot water; add to the mixture, stirring all well. Pour into a wet mould; turn out when cold and set; decorate with holly, and serve with cream or custard. (Secretary, Mrs. Skinner.)

KANGARILLA.

August 17th.—Attendance, 10.

BISCUIT RECIPES.—*Date Biscuits*—Three cups flour, 1 teaspoon cream tartar, $\frac{1}{2}$ teaspoon soda, $\frac{1}{2}$ cup sugar, 1 cup butter, 3 eggs. Add a little milk if required. Roll out, spread half with dates, cover with other half, cut into squares, and bake. Ice the top and sprinkle with cocoanut. Jam can be used instead of dates. *Sunbeam Biscuits*—Two cups flour (S.R.), $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup butter, 1 egg, and very little milk. Mix flour, sugar, and butter well together with the egg and milk. Roll out very thinly and spread with raspberry jam and roll up as for roly-poly. Cut in narrow strips and bake in a moderate oven. *Biscuit Making* (Mrs. Turner)—Biscuits can be made to look very attractive by different icings and fillings and by having a number of fancy cutters. For most biscuits the butter and sugar are rubbed into the flour, the eggs well beaten, and mixed into a soft dough, rolled very thin, and cut into shapes and cooked in a quick oven. Most biscuits will keep for weeks crisp and nice if kept in airtight tins. (Secretary, Mrs. M. Steer.)

LAUBA BAY.

August 8th.—Attendance, 11.

HOME CLEANING AND POLISHING.—Mrs. Burk read the following paper:—"Choose a bright sunny morning when intending to give a room a thorough cleaning, then commence by opening doors and windows. Take down the curtains and hang on the line in a shady place if possible. Cover any furniture—after dusting it—with an old patched sheet, then sweep the walls. Sweep under the linoleum, being careful to lift evenly to avoid damaging it in any way. After the floor has been well swept, dust again carefully, not forgetting to pull out all drawers and dust all the ledges on which they rest. Scrub inside all drawers with warm, soapy water and sanoper, then stand them in the sun to dry. Wash all the furniture with hot, soapy water. When dry, apply floor polish with a soft cloth. To ensure a good polish, apply polish thinly and evenly, then rub briskly and lightly with a soft cloth. Scrub the floor, using sanoper on any marks that are obstinate. Use sanoper sparingly as it will remove pattern if used too much. After the floor dries, polish. When using the mop after sweeping a polished floor, place a soft piece of cloth under the mop. This prevents the mop from soiling easily. Dip an old piece of fuji silk in a vessel in which a

Port Adelaide and Wallaroo.

dessertspoon of plate powder has been dissolved in a cup of methylated spirits. When dry, this makes an excellent cloth for polishing stainless cutlery. Wipe the front of the stove with a piece of cloth that has been dipped in kerosene, let it dry before using the polish. The kerosene removes any grease spots that may be there. If linoleum that looks dusty after being swept is rubbed over with a cloth dipped in kerosene the pattern will appear quite bright again."

ONION PICKLES.—Recipe supplied by Mrs. Edson.—Four pounds of large white onions, 3 tablespoons mustard (heaped), 2 tablespoons flour (heaped), 2 teaspoons tumeric, 1 cup sugar, enough vinegar to cover. *Method*—Cut onions in slices, put in saucepan with vinegar (enough to cover), boil for 15 minutes. Mix flour, mustard, and tumeric with a little cold vinegar. Add this and cup of sugar to boiling pickles and stir. Cauliflower or cucumber may be added if liked. (Secretary, Mrs. D. Morrison.)

MILLICENT (Average annual rainfall, 29.76in.).

August 18th.—Attendance, 11.

Various questions were brought forward and discussed. The following recipe for Peanut Biscuits was tabled:—One small cup of sugar, 1 cup butter, $\frac{1}{2}$ cup treacle, 2 eggs, enough flour to make a soft dough. Take brown skin off a cup of peanuts and mix in dough. Cut into rounds and bake in a moderate oven till a nice brown color. (Secretary, Mrs. M. Hutcheson.)

PINNAROO (Average annual rainfall, 14.54in.).

September 1st.—Attendance, 14.

HOME-MADE DRINKS AND CORDIALS.—Mrs. H. Ahrens gave the following recipes:—

Sugar Beer.—2galls. water, 1 cup each hops and wheat, 1oz. bruised ginger, 1 $\frac{1}{2}$ lbs. sugar. Place hops, wheat, and ginger in fine muslin bag. Boil for 1 $\frac{1}{2}$ hours. Bottle when cold, placing one raisin in each bottle, and cork well. Make early in the morning, and bottle same day. Ready for use in 3 or 4 days. *Ginger Beer.*—1 cup each hops, whole ginger. Cut up raisins and wheat. Boil 1 hour or more. Strain on to 3lbs. sugar, add 3galls. water, and bottle beer from the last lot brewed, or to start beer first a bottle of lager or bitter beer will do. Bottle and cork tightly. Ready for use in 3 days (sooner than that after bottles are seasoned). *Stone Jar Ginger Beer.*—Pour 2galls. boiling water over 2 $\frac{1}{2}$ lbs. sugar and 2ozs. crushed ginger, peel and juice of 2 lemons, $\frac{1}{2}$ oz. cream of tartar. Cover pan, and leave until nearly cold. Add 2 tablespoons yeast, and leave to ferment for 2 days. Then strain and bottle in small bottles, with corks securely tied down. *Hop Beer.*— $\frac{1}{2}$ lb. hops, 4ozs. raisins, $\frac{1}{2}$ lb. ginger, 4ozs. wheat, 4lbs. sugar, 4galls. water. Boil all together for about 1 hour. Strain, and add beaten whites of 2 eggs. Stand for 12 hours; bottle and cork well. *Lemon Syrup.*—2lbs. sugar, 2ozs. citric acid, 1 quart boiling water, 2 teaspoons essence lemon. Mix acid, sugar, and essence in a bowl, and pour on boiling water. Bottle when cold. *Raspberry Balm.*—2 cups sugar, 4 cups boiled water. Remove from fire, and add acids to taste. When cold, add essence of raspberry, cochineal coloring, and a little vinegar. *Lime Juice.*—3lbs. sugar, $\frac{1}{2}$ gall. water. Boil 10 minutes. Let cool, then add 60 drops essence of lemon, 2ozs. acid, $\frac{1}{2}$ teaspoon carbonate soda. *Cordial.*—Cut 1 stick rhubarb into small dice. Place in jug, with 1 tablespoon of sugar. Pour $\frac{1}{2}$ pint boiling water over, and stand until cold. *Ginger Beer.*—Put on in a saucepan 2 cups of sugar, 2 dessertspoons cream of tartar, 1 teaspoon tartaric or citric acid, with enough water to dissolve it. Put in a gallon jar, and fill with water, or just add a gallon of water, and bottle. *Chili Wine.*—2 small cups white sugar, 1 heaped teaspoon citric acid, 14 chilies, 1 dessertspoon essence lemon. Put in a large bowl, and pour on 2 quarts boiling water. Add a little burnt sugar to color. Essence of lemon and burnt sugar to be added when nearly cold. *O.T.*—49 chilies, 12 cloves, 4 cups sugar, 2qts. water, and 1 teaspoon tartaric acid. Boil $\frac{1}{2}$ hour, strain, and when cold, add 1 teaspoon essence of lemon. *A Nice Drink.*—1 gall. water, 3 lemons cut in halves. Boil lemons in water, and while boiling add 1lb. sugar, and stir till dissolved. Pour over 2 teaspoons cream of tartar, and stir well. When cool, bottle and cork tightly. Keep two weeks; then ready for drinking. *Lemon Beer.*—1gall. boiling water, 1 sliced lemon, 1oz. bruised ginger, 1 teacup yeast, 1lb. sugar. Stand for 12 hours, and it is then ready to bottle. *Ginger Ale Syrup.*—4lbs. sugar, 2ozs. white ginger, 1 tablespoon each cream of tartar and citric acid, about 36 chilies, and 2 quarts water. Boil all together for 20 minutes, and color with burnt sugar. *Boston Cream.*—2 cups sugar, 4 cups water, 1oz. tartaric acid, 1 teaspoon essence lemon, and white of 1 egg. Dissolve sugar in hot water, and when cold add acid, essence of lemon, and white of egg beaten stiffly. Put small quantity in glass, add cold water, and stir in $\frac{1}{2}$ teaspoon carbonate soda. *Hop Beer.*—3oz. hops, 2ozs. bruised ginger, 2lbs. sugar, 3galls. water. Put on to boil for 1 hour. Then strain, bottle, and cork when cool. (Secretary, Mrs. F. Atze.)

RENDELSHAM.

August 30th.—Attendance, 15.

SPRING CLEANING.—Mrs. Todd read the following paper:—"Blankets, &c., should be washed while plenty of rainwater is available. Turn out drawers, wardrobes, cupboards, boxes, &c. Drawers can be covered with towels or paper to keep out the dust. This will bring to light old garments that can be used for dusters, rubbers, &c., which, when dirty, can be burnt. Small ornaments and pictures can be cleaned and packed into bath tubs. A fine day should be chosen for emptying and wasling bed ticks. An unbleached cover slipped over the bed and removed for washing twice or so a year helps to keep the bed clean, and also saves loss of feathers and kapoc, &c. Pillows can be done in the same way. New blankets and curtains should be placed in cold water a few hours or overnight. Very smoky curtains must be put through several waters to remove as much of the smoke as possible before actually washing. Put the lace and muslin curtains through the wringer or squeeze them by hand. Wringing breaks the mesh and ruins the curtains. When clean shake the curtain and hang them lengthwise on lines to dry. Afterwards pull into shape before ironing, for which only thin starch is needed. Cloudy ammonia and Lux are good for blankets and woollens. Wash and rinse in several waters until clean, then shake and dry. Clear out of the rooms all movable articles, and cover those left with dustsheets and paper. Open doors and windows, and sweep walls and ceiling with a soft broom. Chimneys should be swept by pulling up and down a pine branch, and the soot placed in the garden. Sweep floor well, and burn all fluff and dust. Window frames, doors, and skirtings should be washed with soapy water and flannel. Wash varnished walls and doors with warm water and vinegar, and polish with window leather or furniture cream. Window blinds are best laid on a table and cleaned, because they never hang so well when washed in the usual way. Wallpapers can be cleaned with a dough made from flour and cold water. All loose whitewash, kalsomine, or wallpaper should be removed by washing with an old whitewash brush. Before using kalsomine suitable colors should be chosen for each room. Wire mattresses can be rubbed well with kerosene and flannel, the woodwork polished with furniture cream, and carpets hung on a clothesline and beaten. Cold tea is useful for renovating a carpet. Put beds, blankets, curtains, hangings, &c., out to freshen whilst cleaning the room. Always wash floors as soon as possible after using kalsomine. Strong soda and hot water is good for removing smoke from the ceiling and walls. Wash around the stove with a whitewash brush. See that floors are thoroughly dry before putting down the coverings. Place plenty of papers under linoleum. A sprinkle of borax is good to keep away silverfish and moths in spare rooms. When sweeping a carpet take off the dirt then go over it again. A carpet sweeper is very good for taking up crumbs, &c., after each meal. Glassware should be cleaned with a nail brush. Red paint is very good for finishing off hallways, fireplaces, hearths, and flowerpots. Silverfros is very good in many ways, but black-lead is best for hard wear for stoves where there is a family and continual cooking. A little kerosene or methylated spirits is good in the water for cleaning windows, and helps to keep away the flies. A color scheme can be worked out in the kitchen by painting chairs, dressers, tables, frames of pictures, with curtains and cushions to match. The kitchen or living room is the place where a good many hours of one's life are spent, and should be made bright and cheerful. Coconut matting and grass mats are cleaned by placing on verandah and washing with soap and water. A window leather is good for a final rub over all paint work. Do not forget to examine picture cords or wires. Rub over leather furniture with a little oil and vinegar. After removing dirt from all rooms go over all with a final polish. A polish at Christmas keeps things in good order." (Secretary, Mrs. E. Andrews.)

SADDLEWORTH (Average annual rainfall, 19.55in.).

September 8th.—Attendance, 8.

SUMMER FLOWERS.—The following paper was read by Miss Frost:—"It is advisable to wait until October to sow flower seeds, because they germinate more quickly during warmer weather. Sometimes when sown in September, and the plants come up well, they are checked by a cold spell, and once this happens they seldom thrive afterwards. Summer seedlings should come up quickly and keep on growing to make healthy plants. The best method is to sow the seeds in open seedbeds, dividing them into sections, but petunia seeds should be in boxes. All fine seeds should be mixed with sand when sown. The soil of seed-beds should be composed of light sandy loam. The surface should be pressed down evenly and firm, and after a good watering the seed should be sown and covered with light sandy soil. Dry stable manure should be dusted over the surface to keep it from being washed about when the bed is watered. It will also permit the young plants to come through easily. It is advisable to have a watering-can with a

very fine rose. The petunia, on account of its hardiness and free flowering habit, is very popular for the summer garden. It requires very little water, and flowers freely during the hottest weather, continuing to flower right up to winter. A mixed bed of phlox gives the most satisfaction, although very beautiful effects can be secured by growing separate colors. October is the best month to plant asters. Zinnias should be planted in beds during November or December and transplanted. Salpiglossis should be sown where it is to be grown, because the plants do not appreciate transplanting. They should be thinned out to 9ins. apart. Delightful effects can be secured with antirrhinums by growing different colors. Delphiniums should be sown in September and will then germinate very quickly. Dwarf varieties commence to flower in January. Iceland poppies, pansies, violas, and stocks sown in January give good winter results. If the plants are forced with sulphate of ammonia at the rate of 2ozs. to a kerosene bucket of water during winter, success will be assured." (Secretary, Miss G. Frost.)

WARCOWIE (Average annual rainfall, 11.42in.).

August 29.—Attendance, 15.

REARING TURKEYS.—The following paper was read by Miss D. Sanders:—"When setting turkey eggs be sure that they are fertile. The hen should sit on the eggs for four weeks, but if they are not all hatched by then leave them a few days to make sure there are no chicks left to perish in the eggs. About a day or two before they hatch sprinkle the eggs with warm water, and continue doing so until the eggs are chipped. Be careful not to have the water too hot or it will injure the chicks. Young turkeys need careful feeding—hard-boiled eggs and green onion tops or curds and pepper make an excellent feed for them. After a week or so they may be fed on bran mash; pollard is sometimes used, but that is not to be recommended. Turkeys must be kept in a warm spot. They are very sensitive to cold, and even after they reach the age of three months a very cold change will often kill them. October is a very good time to start to rear turkeys when the greenfeed is about and the weather is getting a little warmer. Turkeys begin to lay when they are about 12 months old. They lay between 20 and 30 eggs before they go on the brood. Older hens are preferable for setting purposes, because young hens are likely to leave their eggs before they are ready to hatch." (Secretary, Mrs. A. Crossman.)

WARRAMBOO.

July 21st.—Attendance, 14.

HOME REMEDIES.—Paper read by Mrs. J. Sampson:—"The following simple home remedies have proved most effective. When a child is 'out of sorts' give an opening dose of one large dessertspoon of castor oil and repeat if necessary. When a cold settles on a child's chest the best thing to do is to rub the chest and between the shoulders with warm camphorated oil night and morning, and if the cough is troublesome at night, a dessertspoon of olive oil will stop the tickling of the throat and allow the child to go to sleep. *Croup.*—The throat should be kept warm with flannels wrung out in very hot water. Give 1 dessertspoon of half olive oil and half honey. Repeat every hour if necessary. If croup is taken in its early stages this will work an entire cure. *Burns and Scalds.*—Carbonate of soda or cornflour gives instant relief. It may be applied either wet or dry to the burned part and will draw out the heat and pain. The white of an egg smeared on the burn or scald kept moist and exposed will also give relief. Iodine is valuable for cuts and wounds. To prevent spread of an infectious disease, cut an onion in four parts and put in the sick room."

Paper read by Mrs. L. Adams:—"Prevention is better than cure. When going out into the cold after being in a warm room or going out after a warm bath, a dose of spirits of camphor will prevent one catching a cold. If one feels a cold coming on it is also good to take, as also is a dose of ammoniated quinine. Colds should be taken great care of from the start. Eucalyptus is useless to take after a cold has a good hold, but in its early stage it will often break a cold, as camphor and quinine do. When the colds are tight on the chest or symptoms of bronchitis, a few doses of bryonia will work wonders to loosen the cough, taken alternately with aconite if very feverish, or belladonna if there is a headache. A mustard poultice is a great help for bronchial colds. For children, a good plan is to cut a piece of flannel—like a front that is worn under boys' blouses—saturate or make it moist with olive oil, and rub as much dry mustard into it as it will absorb, warm it and place on the child's chest. Leave on until the cold or cough loosens. Give the child plenty of olive oil and sugar and a dose of castor oil, liquorice powder, or fruit salts. *Bowel Complaints.*—For diarrhoea, rest the bowels from 12 to 30 hours; mix together equal quantities of brandy and castor oil, and give 1 teaspoon about every 4 to 6 hours. Give only boiled water to drink, then

rice water or barley water, then light food as the child improves. For sickness, 1 teaspoon to 1 dessertspoon of lime water in the food will often stop sickness; sometimes a little fluid magnesia will stop it also. For burns, keep a tin of picric acid powder in the house. In the case of a burn, sprinkle the powder on the injured part. Saturate a piece of clean white rag and place on the burn and cover the part to exclude the air from it. If picric acid is not at hand, olive oil placed on the burn at once and covered with bicarbonate of soda is good, and if done at once the burn rarely ever blisters. Carron oil is another useful remedy. This consists of equal quantities of olive oil and limewater. To make limewater, place a piece of unslaked lime about the size of an egg in a bowl and pour a quart of water on and stir before using; when settled use only the clean lye. *For Sore Throats*.—A little powdered alum, sulphur, or borax placed on the back of the tongue will often give relief. It is very handy to have a gargle in the house that is always ready to use. It is made as follows:—1 teaspoon each of carbonate of soda, powdered borax, sugar, and salt. Pour over these a cup of boilnig water; when cold bottle and gargle the throat frequently. This gargle is also good for tonsillitis. *For Cuts*.—If there is dirt in the wound wash thoroughly with boracic—1 teaspoon to 1 pint of water, or water with a few grains of Condy's crystals added to it. To stop bleeding, pour eucalyptus or Friar's Balsam on the cut. If these fail use a little flour, pepper, or chewed parsley. When the wound is cleansed and the bleeding stopped, take a clean piece of rag and apply vaseline or boracic powder. The following recipe for an ointment:—Render 1lb. of mutton suet, add 1 large pot of vaseline, 2ozs. boracic powder, 1 tablespoon of sulphur, $\frac{1}{4}$ bottle of eucalyptus. Mix all thoroughly together into the rendered fat; place in jars and tie down with butter paper. *For Bad Eyes*.—If poultices are needed, camomile flowers are very good, as also are tealeaves. A little vaseline smeared on the eyelids of children at night will keep the lids from sticking together. *For Earache*.—A few drops of warmed olive oil will often give relief. Warm it over a candle in a spoon and pour it in the ear. A little piece of onion toasted and placed in the ear while warm is another good remedy, as also is a bit of wadding with a little bit of pepper on it. Syringe the ear with a little carbonate of soda water; this will give relief or stop it immediately. Toothache is often due to decayed teeth. A piece of wadding with a drop of eucalyptus, Friar's Balsam, oil of cloves, or essence of lemon can be used. If an abscess is the cause of the trouble, a bag of hot salt or the hot water bag seems to be the only way to get ease. However, a visit to the dentist is strongly recommended. *For Bruises*.—A tube of capsolin is a very good thing to keep in the house. A piece of raw beef or treacle on brown paper will also draw out the bruise." (Secretary, Mrs. A. Steer.)

October 13th.—Attendance, 11.

PREPARING A CHRISTMAS DINNER.—Paper read by Mrs. A. Hampel:—"I prefer a cold dinner for Christmas. *Meats*.—Roast seasoned turkey, boiled ham, and a choice piece of corned beef—all these meats to be cooked the day before, so that they will be firm and cold to carve. *Salads*.—Tomato, cucumber, and red beet salads are usually what I prepare. Tomatoes are cut in rings, sprinkled with a little salt, and a little vinegar added. Cut cucumbers in thin slices, cover with fresh separated cream, and add sugar. The red beet is done in the same way as the tomato salad, only sugar is added. Mashed potatoes are also served. *Dessert*.—A boiled plum pudding and baked apple pie and vanilla custard are also served. The pudding is cooked three to four weeks before and hung to dry, then it only needs two hours boiling before being ready for use. Usually after all these have been partaken of a little bread and butter, and fresh fruit and nuts and sweets are all that is needed."

PREPARING A CHRISTMAS TEA.—Miss J. Patterson read the following paper:—"In preparing a Christmas tea the Christmas cake is the most important item. Make the cakes about a fortnight before Christmas, and put them away in an airtight tin until about a couple of days before Christmas, then ice and decorate them. Turkey and ham is usually served. There are always so many fruits, sweets, and different kinds of nuts to eat on Christmas Day, that by the time tea is ready it is difficult to enjoy the good things that have been prepared."

CHRISTMAS GIFTS.—Mrs. A. Collins read the following paper:—"A handkerchief satchel makes a very useful gift, especially when on holidays. Make a scarf or dress hanger, knitted with scraps of wool, underline with colored silk to tone with the wool, and put a stocking hanger on to the dress, or another hanger at the bottom hanging on ribbons from the top; this is very handy for hanging the evening dresses. Traced worked aprons also make nice presents, but are hardly serviceable for the farmer's wife who has so much washing to do."

CHRISTMAS GIFTS.—Paper read by Mrs. P. Daniel:—"It is not always the most expensive gifts that give the most pleasure. Often quite a small article made by the giver is most acceptable. There are dozens of things that can be made in a very

short time out of scraps of material. What is nicer than a patchwork cushion stuffed with feathers or wool? The trouble is usually to find time to sit on it. A pair of feather pillows is a very useful present, especially for a girl getting her box ready. A pair of tea towels with the initials of the recipient worked on is also very useful. For a person who is fond of gardening a few packets of seeds that have been gathered and put neatly in packets inside a square tobacco tin which has been lacquered some bright color and a photograph of your garden stuck on the top makes an attractive present. A pot plant or two will be acceptable, the tin painted or covered with a piece of cretonne or wall paper. A needle case is a most useful article, the outer leaves of which can be made from pieces of an old felt hat and embroidered with gay scraps of wool; the inner leaves being made of flannel in which to keep pins and needles. Half a dozen kettle holders bound with contrasting material and put in a neat bag to hang up, and some pieces of sugar bag with the edges bound for oven cloths will be most acceptable to a woman who spends most of her time in the kitchen." (Secretary, Mrs. A. Steer.)

WASLEYS.

August 3rd.—Attendance, 29.

APPLES AND THEIR USES.—Miss L. Hewlett read the following paper:—"Apples, like all other fruit, must be fresh and clean if the best results are to be obtained. They must be kept in a cool place and handled carefully, because they bruise very easily. Apples are one of the best fruits for health, and especially for children. There are numerous ways of using them; baked apples with a few cloves are delicious with cream or custard, stewed apples and custard, apple pie and cream, stewed apples put in a piedish and Empire crackers placed on top and baked a golden brown and served with cream; apples with rhubarb make a very tasty dish—it takes the sharpness off the rhubarb. Recipes for using apples:—*Apple and Lemon Tart.*—Six medium sized apples, 1 lemon, small cup sugar, piece butter, 1 egg. Melt butter in a saucepan, add half the lemon rind grated, then the juice. Add apples cut finely and cook until tender. Add beaten egg and cook a few minutes longer. Put on pastry and bake. *Baked Apple Dumplings.*—Make a crust of short pastry; $\frac{1}{2}$ lb. dripping, lard, or margarine to $\frac{1}{2}$ lb. flour, also baking powder. Mix pastry rather dry. Peel apples finely and core them. Roll out pastry thinly and cut into circles large enough to cover apples. Place each apple on a piece of pastry and fill the centre with currants or brown sugar. Close up the pastry around them and pinch the edges together on top. Place the dumplings on a slightly greased tin and bake in a moderate oven for half to three-quarters of an hour. Just before cooked put a little brown sugar on top of each. This makes a sweet coating but be careful that it does not burn. *Boiled Apple Dumplings.*—Make a suet crust with $\frac{1}{2}$ lb. chopped suet, $\frac{1}{2}$ lb. S.R. flour, pinch salt, $\frac{1}{2}$ pint cold water. Put the flour, suet, and salt in a bowl, stir all together, add water and mix to a paste. Roll out to about $\frac{1}{4}$ in. thick, then cut into rounds—depending on the size of the apples. Put an apple previously peeled on each piece and completely cover. Have ready a large pot of boiling water. If preferred they can be tied in a sponge cloth instead of an ordinary pudding cloth. Plunge them in, boil 30 minutes, and garnish with sugar and cream. *Steamed Apple Pudding.*—Make suet crust with 2 cups flour, 1 teaspoon baking powder, 1 cup chopped suet. Mix to a stiff dough with water. Roll out and line a basin. Peel and core apples and cut into thin slices until the basin is full. Cover with pastry and put in a saucepan of boiling water and steam two hours. Take up, cut out the top and put in 1 cup of sugar and a little nutmeg. Stir until sugar is dissolved. Put on top crust and serve with cream or cornflour sauce. *Apple Hedgehogs.*—Choose good, large cooking apples as near the same size as possible. Pare and core them, being careful not to break them. Roll up the apple parings into piles and place one in the centre of each apple; brush over with white of egg and put aside until quite dry, then brush over again with white of egg and sprinkle with castor sugar. Put apples neatly into a piedish, cover with greased paper, and bake in a slow oven until tender but not in the least broken. When done, remove the apple paring and fill the cavity with blackberry, black currant, or red currant jelly and let it set. Have ready some blanched almonds, cut into thin spikes, and stick the apples over with these. Serve cold with apple syrup. *Apple Syrup.*—Cook a large apple in well sweetened water, flavored with lemon juice and cloves. Strain before serving with apple hedgehogs. *Apple Sauce.*—About $\frac{1}{2}$ lb. of apples, 2 cloves, 2 tablespoons each water and sugar, 1 teaspoon butter. Peel, core and slice apples, put on with cloves, sugar, and cold water. Simmer gently until tender. Remove cloves, mash with a fork, add butter, and re-heat. If apples are not juicy, a little more water may be added. *Apple Chutney.*—3 lbs. each apples, onions, and sugar, 1 $\frac{1}{2}$ ozs. cloves (bruised in bag), 2 lumps garlic, 1 teaspoon cayenne, 3 teaspoons salt, 1 teaspoon ground allspice, 1 bottle vinegar (large), $\frac{1}{2}$ lb. sultanas. Boil 3 hours slowly. If apples are ripe use $\frac{1}{2}$ lb. less sugar. Mince the apples and onions." (Secretary, Miss G. George.)

SIDELINES.

(Paper read by Miss B. Day at the August meeting of the Wasleys Branch.)

DAIRYING.

Although Wasleys is a purely agricultural district, times of adversity have led us to adopt mixed farming rather than petty cash sidelines. The sidelines usually left in the hands of the housewife are the dairy, poultry, and garden. The average farm of this district is 500 acres, and will thus easily allow for the pasturing of 6 or 8 cows. If there are no daughters in the home then it is essential that help be procured. Six or eight cows will pay for the help, and enable us to still further expand our interests. The cows will show a net profit of 10s. per week after allowing for all milk, cream, and butter used in the home even with the very low price of 9d. per pound for butterfat. Although the fodder is grown on the farm, hay cannot be produced for less than £2 a ton and show a profit over working expenses. Bran is undoubtedly the best concentrate, it produces more butter of the best flavor, but at present prices something cheaper must be fed. Oats are the best substitute, and when well crushed will be a close second to bran. Salt and bonemeal are two essential articles in a cow's ration; thus the expenses show:—17 tons of hay, £34; 3 tons of bran, £16; 1½ bags of salt, 7s. 6d.; bonemeal, 14s. 6d.; total, £51 2s. 6d. It is advisable to have five cows in fresh milk during the first six months of the year, one during January, four spread over the months of March, April, and May, and one in September. This will provide good returns when the market is at its peak. One or two selected heifer calves should be reared each year if possible, so that the herd is always young and at full profit.

POULTRY.

Poultry plays an important part in assisting to balance the farm budget. South Australia is one of the largest exporters of eggs in the Commonwealth, and a wide avenue is open for increased revenue in this direction. Although much extra handling is necessary in selling eggs direct to any one of the export companies, the increased return shows a considerable profit over and above the expense. Two hundred fowls will return more than £100 against expenses of £33 for 70 bags of wheat at 8s. 6d., £29 15s.; bran and meal, &c., £3 5s.; total, £33. Shell grit can be obtained when visiting the local beach. Green feed is most important, and fowls should have large quantities of chaffed lucerne, &c., all the year round, whether they are on free range or penned. The best hatching periods are from the end of January to April, and July to October. Chickens hatched in January and early February grow rapidly, and lay when eggs are dear. I prefer the White Leghorn and Black Orpington or Minorca cross. They always sell well as table birds when the laying period is spent, and the young cockerels find a ready market either live weight or dressed and sold privately. Turkeys show a good return if hatched early in August and September so that they will grow quickly on the green grass. Turkeys which do not fatten when very young are hard to get to prime table birds at the right age. They need scrub shelter and distant neighbors. They are inclined to wander to the adjoining crop when one is engaged in home duties. Ducks and geese show a good return during the festive season.

SHEEP.

One hundred sheep can be carried on a farm of 500 acres—40 ewes and lambs and 20 sheep for the farm mutton supply. Any ill luck the farmer may experience in losing the ewe, or the mother refusing to care for the lamb, is the good fortune of the housewife, for she is able to rear the orphan on cow's milk with a little trouble and then collect the cash. Sugar should be given in the milk—fresh milk for a week, and this gradually diluted until the skimmed milk is used. The tallow from the mutton supply can be used for candle or soap making, or sold to the merchant with the skins.

GARDENING AND NEEDLEWORK.

The home garden is a sideline which is often not used to any appreciable extent. With a little help from the men in the way of carting manure and digging a number of fruit trees and vegetables can be grown for most of the home requirements, and one is able to have better preserves and jams because of the quality of the fruits.

Needlecraft is an outlet for the finer art of the housewife. Many useful and attractive gifts can be fashioned, and if not sought near at home there is always the open opportunity of becoming a member of the Women's Work Depot in Adelaide, which undertakes to sell any article of woman's work on a commission basis.

WEPOWIE.

* August 1st.—Attendance, 14.

CAKE MAKING.—Paper read by Mrs. J. Burns: "Success in cake making is an acquired art gained through a careful attention to detail and experience. Annoying though it may be to admit it, recipes are very seldom wrong. Failures can generally be traced to a fault on the part of the cook. Beating is very important. Heavy cakes can generally be attributed to insufficient beating. With sponge cakes the whites of the eggs should be beaten stiff, then the yolks and sugar added and beaten; and with butter cakes the butter and sugar, then eggs, must be beaten until light, creamy, and full of air bubbles. A well beaten cake can hardly fail to be light. Flour should not be beaten in, but stirred or folded in lightly, and the cake should go into the oven as soon as possible after mixing. Home made self-raising flour is always reliable, and by mixing $\frac{1}{2}$ lb. cream tartar, $\frac{1}{2}$ lb. carb. soda, a little salt with 16 lbs. of flour a good supply of self-raising flour is always on hand. Quite a variety of cakes can be made from the following foundation mixture:—*The Mixture.*—Beat $\frac{1}{2}$ cup of sugar to a cream with 2 tablespoons butter, add 2 eggs, 1 cup milk, 2 cups S.R. flour. Drop some of the mixture into hot gem irons, and cook. When cold, ice with vanilla-flavored icing, roll in cocoanut, and snowballs will be the result. Ice with chocolate icing, cut off top, fill with whipped cream, replace the cut piece, and chocolate creams are made. Another way is to cook the mixture in paper patties—dates, nuts, or currants or any flavoring added—and by using different colored icings and decorations a variety of small cakes can be made. A set of icing tubes is helpful, using cream instead of icing to make roses and scrolls. Lamingtons can also be made from this mixture, and for variety dip the cubes in melted jelly then in cocoanut, or use lemon-flavored white icing and call them lemon snows. This mixture also makes a nice plain cake if cooked in a moderate oven for $\frac{1}{2}$ of an hour. *Recipes for Party Occasions.*—Eclairs: Eclairs are usually iced or decorated with chocolate glaze or icing, and filled with whipped cream coffee icing, and a coffee flavored custard make yet another variety. Put 1 cup water and 1 tablespoon butter into a saucepan. When boiling take off fire and stir in 1 cup S.R. flour, beat well, then beat in 3 eggs, each one separately. Put into a forcing bag or biscuit forceer, and force out on to a greased baking sheet in lengths of 3 in. Cook them for $\frac{1}{2}$ an hour. Have the oven hot at first until they rise, then reduce the heat to moderate to set them. *Merengues.*—Whites of 3 eggs, $1\frac{1}{2}$ cups granulated sugar, $\frac{1}{2}$ teaspoon vanilla. Beat egg whites until

SUNSHINE STRIPPER HARVESTER

THE LIGHT DRAUGHT MACHINE.

Manufactured in
8ft. and 10ft. sizes.

Special Attention is drawn to our New Attachment
The SUNGUIDE COMB CLEANER
which will handle all tangled and weed infested Crops.

95-97, NORTH TERRACE, ADELAIDE.

(H. V. McKAY MASSEY HARRIS PTY. LTD.)

stiff, add slowly sugar, and continue beating until mixture holds shape. Drop by spoonful on unglazed paper, and bake in a very slow oven for 30 minutes. Then increase heat a little, and bake 30 minutes longer. Remove from oven, push the underneath portion in to form a cavity, fill with whipped cream, over which sprinkle a little cocoa, and decorate with a blanched almond. Do not fill meringues until just before serving. Peaches: 2 cups S.R. flour, 1 cup sugar, $\frac{1}{2}$ cup milk, 1 tablespoon butter, 2 eggs. Beat sugar, butter, and eggs together, add milk and flour, bake in hot gem irons for 8 minutes. When cold, cut off tops, and press 2 together to form a peach with whipped cream or raspberry jam. Paint outside with carmine which has been diluted in water, and when nearly dry roll in castor sugar. Decorate with a piece of angelica for stem." (Miss E. Roocke.)

WILLIAMSTOWN (Average annual rainfall, 27.7in.).

September 6.—Attendance, 5.

HOW TO DRY FRUIT.—Mrs. W. Patterson read the following paper:—Have the water boiling in the copper, and to each 12galls. add 1lb. of greenbank lye. The water must be kept as close to boiling point as possible through the dipping process. Plums should be immersed for 6 seconds in the lye; then withdrawn, and plunged again into clean water. The second dip should be only of short duration. The fruit is now placed on trays, and is ready to go out on the drying green. If the dip has been successful the fruit will show a roughened skin, covered with numerous small cracks. If the fruit cracks or splits, then perhaps the lye has been too strong. If the weather is favorable the fruit will dry in a week. On dewy, damp, or rainy nights stack the trays to keep the fruit dry. A pan of sulphur put in a sulphuring box improves the color of light fruit. Recipe for dried apricots:—1lb. of dried apricots, 1 dipper of water, 6lbs. of sugar. Soak apricots for 2 days before boiling; then boil until a nice clear color. (Secretary, Mrs. A. Cundy.)

PAPERS READ AT PINNAROO LINE CONFERENCE.

[Parulla, September 26th, 1932.]

JAM AND JELLY MAKING.

[By Mrs. BONNIN, Pinnaroo.]

For the successful making of good jam, good quality ripe (but not over-ripe) fruit is necessary. All defective parts should be cut out. One must not expect good results from inferior or fermented fruits.

The fruit is prepared in different ways for the various jams. Some prefer to cut it in small pieces, while others favor half or whole fruit. The former method is more economical, but the latter is always used for a conserve. With some fruits, it is necessary to add sugar, or a portion of it, overnight; this hardens the fruit and the pieces almost retain their original shape. Another way to make a good conserve is to boil the sugar and water and then add the fruit pieces and cook gently until done, stirring as little as possible in order not to break the fruit. With some fruits it is unwise to add the sugar overnight, namely, some varieties of plums, quinces, &c. The sugar hardens the outsides of the fruit, and, when cooking, it is impossible to cook the centres of the pieces; particularly is this so with melons. Such fruit as quinces, apples, melons, and pears require a long slow cooking to obtain a good color. The berry fruits, raspberries, &c., require quick boiling to ensure good color and flavor.

The amount of sugar also varies with different varieties of fruits. The general rule is 1lb. sugar to 1lb. fruit, but with some jams 1lb. sugar to 1lb. fruit is essential. With the extra weight of sugar one obtains a greater weight of jam, so that the added expense is not all extra. Also the jam is of better appearance, and the additional sugar improves its keeping qualities. If too sweet, lemon juice or tartaric acid may be added to taste, the latter being preferable because it has no flavor. Crystal sugar is usually recommended for jam making, but the ordinary A1 white is quite good.

Always use an enamel or aluminium vessel, and watch carefully, stirring at intervals to prevent burning. This is particularly necessary where a vessel has been previously burnt.

The usual method with most jam making is to boil the fruit, or fruit and water. When boiling, the sugar is added after being previously warmed in the oven. Skim frequently or the jam will not be clear. Some fruits (plums, apples, and melons) which contain pectin, will jell when sufficiently cooked, and these should be tested by putting a little in a saucer and if the jam sets it is ready for bottling. Other fruits, such as apricots, peaches, figs, pears, &c., should be boiled until a nice color and consistency are obtained. One needs experience to know just when the jams are sufficiently cooked, and when cooked the pan of jam should be removed from the fire and bottled as soon as possible. By doing so all air bubbles (which spoil the appearance of the jam) will be excluded. The bottles should be thoroughly dry and heated in the oven while the jam is cooking, otherwise, when the hot jam is poured into cold jars, there will be risk of breakage.

I prefer jam sealed whilst hot, although if one has had enough stickiness for one day it can be quite securely sealed the following day. There are various methods of sealing. For the screw-top jar paraffin wax is quite good. Melt the wax in a clean tin by standing in a saucepan of water and heating it, then pour a little in the jar, tilting it so that the wax clings to the sides of the jar. Then add the screw lid. Good stout tissue paper—two rounds for each jar—makes a good seal. Dip one round in either milk or whipped white of egg and cover with the second round. Paste made from flour and water is a popular method of sealing jam, and there is a purchaseable cold water paste which is also successful. When sealed, the jars should be washed, labelled, and stored in a dry, cool place—a damp storage causes mould, a hot one starts fermentation, and too strong a light will fade the bright colored jams. If apricot or fig is wanted for exhibition purposes, a better color will result if the fruit is peeled. Another good hint is to polish the jars with Bon Ami, which makes the jam look much clearer.

JELLIES.

The special feature of jellies is their attractive appearance. Good jelly, when ready for use, should be firm enough to hold its shape when turned from its jar.

Fruit for jelly is at its best early in the season and slightly underripe. At this stage the fruit contains pectin, the substance which causes the jelly to set. In ripe fruit this substance changes to a fruit sugar and will not jell. Some fruits, such as cherries pears, peaches, &c., contain no pectin of their own, and if a jelly is wanted from these fruits other fruits which are rich in pectin should be added. Apples are to be preferred as they have no distinct flavor of their own. As in jam some fruits require water, while others must be cooked in their own juice. All jellies are made in practically the same way, that is, cut up fruit roughly with skins and seeds included and first cover with water. Berry fruits are crushed a little to draw the juice, and no water is needed. Boil very gently until quite soft and stir as little as possible.

Leave overnight, as more goodness is extracted in this way. Next day strain through a colander then through a jelly bag (first rung out in hot water). On no account squeeze the mixture. Then measure the liquid and to every cup add one cup of sugar. Bring liquid to the boil and then add the sugar which has been previously warmed in oven. As in jams, it is necessary to be sure the sugar is all dissolved before the mixture boils. If this is not done the jelly may crystallise after standing a time. Sometimes it is advisable at this point to restrain the jelly, because the sugar often contains black specks, &c. A piece of muslin or fine cheese cloth is useful at this stage. Boil rapidly and skim frequently. Test from 20 minutes on, as some jellies set quickly, while others require a long cooking. Experience is necessary to tell when the jelly is finished, but the usual methods are to test a little in a saucer, and if, when cool, it can be cleanly cut through with a knife it is done. Another way is to suspend the spoon (with which you are stirring the jelly) above the pan, and if the mixture falls in heavy drops or flakes it is done. Avoid overcooking, which causes crystallisation and little bubbles, spoiling the appearance of the jelly. As with jam, bottle and seal while hot, and store in a cool dark cupboard.

RECIPES.

Raspberry Jam.—Six pounds raspberries, 6lbs. sugar, bring berries to the boil, boil hard three minutes, add warmed sugar, and gallop for five minutes.

Loganberry Jam.—Same as raspberry but boil 10 minutes after sugar has been added.

Red Currant.—Same as raspberry, but straining before adding sugar to remove seeds is an improvement.

Mulberry and Apple.—Five pounds mulberries, 1lb. apples, 4½lbs. sugar, half cup water. Put fruit through mincer, boil 20 minutes, then add sugar and boil an hour or little longer.

Blackberry and Plum.—Five pounds blackberries, 1lb. plums (or apples), 4½lbs. sugar. Bring fruit to boil, boil 20 minutes, then add sugar and boil rapidly until finished.

Gooseberry and Cherry.—Six pounds ripe gooseberries, 6lbs. dark cherries. Place fruit in pan, add two cups water, boil for half an hour, then add sugar, and boil until it jells.

Strawberry.—Four pounds strawberries, 6lbs. sugar. Boil sugar and fruit for five minutes, then add two teaspoons tartaric acid, boil eight minutes, bottle when cold.

Apricot Jam.—Six pounds firm yellow apricots, 6lbs. sugar, one teaspoon tartaric acid, add a very little water to prevent apricots scorching on bottom of pan. Bring fruit to the boil add sugar, and boil rapidly from 10 to 20 minutes. Add acid about five minutes before removing from fire.

Fig Jam.—Six pounds sugar figs, 4½lbs. sugar, the grated rind of one lemon, the juice of two lemons, a little preserved ginger cut fine (6d. for 12lbs. figs), and some blanched almond kernels at the last. Bring fruit to the boil (a little water will be necessary if fruit is very firm), add sugar, rind, and ginger and boil until cooked.

Plum Jam.—Three-quarters of a pound sugar to each 1lb. fruit, fleshy varieties will need a little water. Bring fruit to boil, add sugar, and cook until it jells.

Quince Jam.—Six pounds quinces, 4½ pints water. Boil together until the fruit turns slightly pink, then weigh, and to each pound of pulp add ½lb. sugar. Boil until it jells. If not a pretty red, add a little cochineal.

Gooseberry Jam.—Same as quince recipe, but allow 1lb. of sugar to each 1lb. of pulp.

Dried Apricot and Pineapple Jam.—One pound dried apricots, two quarts of water, 4lbs. sugar, one pineapple, or a tin of crushed pineapple. Cover apricots with water, in which one teaspoon of carb. soda has been dissolved. Soak about half an hour and then rub off skins. Rinse and add two quarts of water, soak 24 hours, then boil gently with the pineapple until the fruit is cooked. Add sugar and boil until a good consistency.

Dried Peach Jam.—One pound dried peaches, two quarts of water, 4½lbs. of sugar, two lemons. Same method as dried apricots.

Melon Jam.—Two pounds melon, 7lbs. sugar, seven cups water, six lemons, two small oranges, cut lemons and oranges, cover with water, and boil until chips are tender, then add to melon and water and bring to boil. Add sugar and boil one and a quarter hours.

THE CULTIVATION OF DAHLIAS.

[By Miss COLWILL, Parilla.]

Every year increased interest is being shown in improvements around the homestead in the way of gardening. To anyone fond of flowers this is an untiring pastime as well as an improvement. There are many kinds of beautiful flowers—roses, sweet peas, carnations, daffodils, dahlias, &c.—but growing dahlias has gradually increased until they have become the most popular.

Dahlias excel most other flowers in their beautiful colorings, and the size of the bloom is much in advance of any other, but this is mainly due to cultivation. They are as easily grown as any other plants and grow well in all parts of this State, provided sufficient water can be given them during the growing period, and especially during the time of flowering. It is a plant that absorbs much moisture, and unless it is kept growing vigorously the whole time, buds may form, but never fully develop.

They can be planted out any time during November and December. In very hot districts the later planting is preferable. A shorter growth is made and flower buds do not form too early, maturing when the hottest of the weather is over. They should not flower until the end of March or in April. The blooms will then be larger, last longer, and retain their color. Without a robust leaf growth, it is impossible to produce large, well-formed blooms. Dahlias make large clusters of tubers to each plant every year. To secure the best results these tubers should be divided and cut with an eye left in each piece. The clusters of tubers should be started into growth before attempting to cut up, and if planted at once the growth continues, and the plant is through the ground in a few days.

It is a good plan when planting the tubers to place in the soil a strong stake at the same time, as if staking is left until the plant is several inches high, there is danger of injuring the roots. Large tubers are not necessary; a small one with a small, prominent eye will make as strong a growth and as good a plant as a large one.

Shade is not necessary, the best flowers being obtained in the open and in rather a sunny position. Too much shade means tall plants with few blooms and insipid colors. It is most necessary to protect them against hot winds. If planted near a hedge, a high fence, or a wall acting as a breakwind, the best results will be obtained.

Although the dahlia will grow in almost any soil, a rather heavy, well-manured loam is best. If the soil is too stiff the addition of well-decayed stable manure well worked in will loosen it. Light sandy soil will be improved by the addition of clay and cow manure. Deep holes can be dug, placing a good layer of manure at the bottom, and filling in with good soil, heavily manured. They like plenty of rich food, ashes and bonedust may be added to each plant. When first planted, water sparingly, increasing the quantity as the shoots make growth, flooding heavily when the first buds form. Do not overcrowd the plants. Plant about 3ft. apart if possible, so that when fully grown the plants get plenty of air and sunlight circulating around and through the foliage.

There are many kinds of dahlias. The Cactus is much admired by some people, others prefer the Decorative or the Collarette. Many pretty shades are seen in the Pom-poms. Recently many beautiful blooms and equally as large in the size of flower, the colors being perfect, have been grown from seeds, which should be sown in September and will flower the first year. Those in the Botanic Garden last April, which were seedlings, were equally as beautiful as those grown from tubers.

THE VEGETABLE GARDEN.

[By Mrs. ATZE, Pinnaroo.]

The best aspect for a vegetable garden is a gentle slope towards the north-east, with a break of trees, shelter hedge, or wooden paling fence as a breakwind on the south, north, and west boundaries; even a good broombush fence will act as a very good break. These conditions are not always obtainable, but shelter from the cold and dry hot winds should always be provided. It is very bad policy to have fruit trees in the vegetable garden, for the continued deep cultivation and heavy cropping does not suit the trees, and on the other hand the shade and the want of moisture caused by them are, as a rule, fatal to the growth of vegetables.

The best soil is a deep, light friable loam, but any ordinary soil can be made into a good garden with ordinary care and attention. Very heavy clay land should be dressed with air slaked lime, about 1lb. to the square yard; a good dressing of ashes and sand may also be applied with advantage. Continued dressings of stable manure tend to lighten clay land and to make it more easily workable. Care should be taken not to work this kind of soil in a wet condition, and whenever any portion of the garden is likely to remain vacant for any length of time, it is a good plan to dig it roughly and leave it in lumps exposed to the wind and sun. This will soon mellow the clay and make the soil friable and easy to work, more especially if it has had a liberal dressing each year of horse or cow dung. There is no better manure than these; horse dung is best for soil on the heavy side. Very light soils are best manured with cow dung and should if possible have a good application of strong loam. Where the soil is poor, there is nothing better than a good dressing of fresh soil taken from the top spit of an old pasture or wood heap. Worked out soil will also be greatly benefited by having green manure crops dug in. Peas are as good as anything, but even green grass will do.

Well-grown vegetables cannot be grown without using plenty of manure. In the ordinary way there is nothing to equal well-rotted stable manure, but where this is not obtainable artificial fertilisers form a very good substitute. The best way to use the artificial manure is in conjunction with rotten weeds, animal refuse, and the like rotted into compost. Many of the artificial manures are too strong to be used with advantage alone, but when well mixed with a compost as suggested leave nothing to be desired. All stable and cow manure should be well rotted before it is applied to the land. Blood and bone manures are excellent, long-lasting manures, but must be used in conjunction with wood ashes and well-rotted stable manure. They contain little or no potash, and a dressing of some other manure containing potash is advisable, especially with such crops as tomatoes, potatoes, and peas. This is, however, not so necessary where good supplies of stable manure or wood ashes are available. Never lime and manure the soil at the same time.

WATER AND IRRIGATION.

It does more harm than good to be always sprinkling the surface. When watering, it is most important that the ground should be thoroughly soaked. If this is done every one or two weeks, it is far preferable to a lighter and more frequent application. The roots will then be encouraged to go down deep into the soil, and will be out of the way of the hot sun and drying winds. At the same time the ground should not be made sodden and boggy, especially if not well drained. It is much the best plan, where available, to have a hose sprinkler. This can be kept going for hours at a time, and it is almost as good as rain.

Another method is to run the water in prepared trenches, letting it soak in gradually. When land is regularly watered, I strongly recommend the practice of mulching, or continually working the surface, otherwise the surface is baked hard, evaporation is encouraged, and the plants are injured instead of being benefited.

RAISING SEED.

The most important thing is to get good seeds. I strongly advise anyone to avoid cheap seeds. The best vegetable seeds are got from good, reliable firms. Small seeds, excepting root crops, are generally best raised in nursery beds, and for this purpose a small portion of the garden should be reserved and sheltered from winds, and with a light sandy and well-drained soil. During very hot, sunny weather it is advisable to shade the beds; some branches of scrub will answer very well. In judging the depth to sow, the size of the seed should be considered, very small seeds being merely covered; large seeds, 1in. to 2in. A good guide is to double the diameter of the seed.

After sowing, it is advisable to give a thorough soaking of water, which in most cases will be sufficient to bring up the seeds. In watering seedlings a fine spray should always be used, or there will be the risk of the plants being washed out. To prevent the surface from caking, a light mulching of well-rotted stable manure or leaf mould scattered over the surface after sowing will keep the surface open and moist. Such seeds as peas, beans, cucumber, melon, trombones, &c., and all root vegetables are best put in rows in their permanent bed, as they are then so much more easily weeded and cultivated.

TRANSPLANTING.

This should always be done in moist, cloudy weather. Give the seed bed a good soaking; then lift the plants with as much soil as possible, taking care not to break the fibrous roots. They should then be carefully planted in rows, the same depth as they grew in the seed bed. They should then be well watered, and if the weather is hot, should be shaded. A few green branches stuck in the ground make a suitable shade. Care should be taken not to plant too closely—the further apart the larger the vegetable. Cabbages and cauliflowers should be at least 2ft. to 3ft. apart.

ROTATION OF CROPS.

To get the best results in the vegetable garden, it is most necessary that different kinds of crops follow each other. Under no circumstances should cabbage follow cauliflower, or carrots succeed parsnips. Each crop should be as dissimilar as possible from its predecessor. A spindle-rooted crop should succeed a fibrous-rooted crop, or *vice versa*. Peas, beans, carrots, parsnips may follow after cauliflowers or cabbage, and would not require any more manure. Carrots, parsnips, or beet should never be sown on freshly manured land, or they will grow mis-shapen and forked. Cauliflower, cabbage, or others of the same family will follow well after peas or root crops, but may have with benefit an extra dressing of well-rotted stable manure. They are gross feeders, and the more manure the better the crop. If the garden is systematically worked in the rotation suggested and regularly fertilised and watered good results should be obtained.

All land under vegetables should be "fallowed" or kept vacant for a few months periodically, as continuous cropping exhausts the soil. A period of rest and exposure to the air has a very beneficial effect in sweetening the soil. To get the most benefit from these the soil should be dug as deeply as possible, leaving all lumps unbroken, and presenting as much surface to the air as possible. In a well-kept vegetable garden, the ground should never be idle. As soon as a crop is off it should either be planted again, or roughly dug and fallowed as directed. Both the condition of the soil and its fertility will be greatly improved, and vegetables can be grown all the year round. In this part of the country, where there is plenty of water, it is not necessary for anyone to buy vegetables.

PUFF PASTRY.

[By Mrs. G. HOLMES, Parilla Well.]

For puff pastry, take 1lb. each plain flour and hard butter, pinch of salt, 1 teaspoon lemon juice, yolk of 1 egg, and 1 cup cold water. Sift flour and salt, make a well in centre, put in yolk of egg and lemon juice, mix with a pliable knife in right hand and a cup of cold water in left. Mix to a fairly soft, workable dough. Knead the dough on a lightly-floured board until it is pliable and smooth.

Then roll it into a strip twice as long as the pat of butter you intend using. Roll the butter in a floured cloth to the same consistency of dough of a flat cake. Then place on one half of paste, keeping it in 1in. from edges; fold over the strip of paste, and seal the edges, to completely enclose the butter.

Let it remain in a cool place for about 15 minutes; then roll out to about three times the original length, but keeping the width the same, and fold exactly in three.

Give the pastry a turn, so that the open ends lie towards you, and roll it out into a long narrow strip, with the same short, quick forward strokes, giving an even pressure with both hands. Again fold the long strip in three, envelope fashion, and then give it another turn to the right.

Continue the rolling, folding, and turning process, repeating six times. The seventh will be ready for baking, taking great care to prevent butter breaking through the paste. Roll to the desired thickness—from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. Brush over with white of egg and a little milk. Heat the oven thoroughly some time before baking, and cook the pastry in a hot oven for 15 to 20 minutes, according to thickness.

If making a fruit pie, hot fruit can be used, but it is necessary to brush the white of an egg under pastry before covering dish. Have an egg cup in dish, and cut a hole in pastry; put into a hot oven. The white of an egg prevents pastry from getting sodden.

The object of cooling between the rolls is to keep the butter and flour in distinct and separate layers.

PASTRY MAKING.

[By Mrs. C. NAPPER, Parilla Well.]

One of the most important qualities in pastry-making is to keep all contents very cool and firm. Dry, and handle as little as possible with naked hands.

When making butter for pastry, I do not salt the butter, as salt brings moisture. Just wash the butter well, and squeeze or roll on boards until quite free from water; then weigh the required amount, and set aside in a cool place to get firm.

The paste should be the same consistency as the butter, *i.e.*, if the butter is nice and firm, so should the prepared paste be firm. To give all pastry a nice finish, glaze with egg.

For meat pies or pasties, glaze with yolk of egg; and for fruit pies, tarts, &c., use the white of the egg.

Rolling.—When rolling pastry, take care not to let any more air than possible escape. This is most important, as the air helps to rise the pastry, and so make the flakes and lightness. Only roll the paste the one way—roll away from you, and do not roll sideways.

Folding.—Fold the pastry carefully after each rolling, and take care to fold the same way each time. Fold No. 1 left side over; No. 2 right side over, the left having three thicknesses of paste; No. 3, take the end of the paste you have been rolling away all the time, and fold towards you; No. 4, the last part, take and fold underneath. You then have a neat square of paste. Press all ends tightly, allowing no air to escape.

RECIPES.

Flaky Pastry.—1lb. plain flour, $\frac{1}{2}$ lb. butter, juice of $\frac{1}{2}$ lemon, little cold water.

Method.—Take the flour and a piece of the butter, the size of a walnut. Rub butter into flour lightly but thoroughly. Scoop out a hole in the flour, and squeeze in the juice of half a lemon, and add enough cold water to mix to a firm paste.

Take out of basin on a lightly-floured board, and roll very thinly. Cut butter in three, and take one-third, and put in little dabs all over paste; fold as explained previously. Repeat this until the 3 pieces of butter are used, making 3 rollings. Fold again. Allow to stand 1 to 2 hours, or all night for preference. Roll required thickness in the morning, and bake in a nice hot oven, but not scorching, or scone-hot.

I use this recipe with a very slight alteration. If butter is very firm I leave the last lot of dabs in paste all night, and bake after the third rolling, and this also makes beautiful, light pastry.

If lemons are not available, use the yolk of an egg, or a sprinkling of cream of tartar. Take $\frac{1}{2}$ teaspoon of cream tartar, and sprinkle over the dabs of butter the first rolling only, and roll as usual. Use as little flour on board and rolling pin as possible, as too much flour roughens.

Lard is a wonderful substitute for butter in pastry making; use half butter and half lard, or all lard makes a very light, every-day pastry for pies, or plate tarts.

FRUIT DRYING AT HOME.

[By Mrs. FOALE, Parilla).]

Drying one's own fruit will prove a pleasing and profitable task if the fruit is purchased at a reasonable cost. Although the profit may not be very great, still it is a consideration in times like these, when every housewife is striving to be as economical as possible. Then again, it is very pleasing to see a nice stock of wholesome, home-dried fruits, such as raisins, sultanas, currants, prunes, lemon peel, &c., stored away to carry on for 12 months. Where the fruit is grown on the farm, such as grapes, it is a wonderful save to be able to dry all the cake and pudding fruits, and it is rather surprising that vines are not more extensively grown in the mallee, where there is a good supply of water. They can be grown with little trouble.

As to the actual costs of dipping and drying when the fruit has to be purchased, last year's grapes could be bought for 6s. per case (approximately 40lbs.), and from this quantity I always get from 10lbs. to 12lbs. of sultanas or raisins. This may seem very little from 40lbs. of fruit after the moisture has dried out, but it pays all the same.

THE NEW MODEL DOMO

AWARDED THREE PRIZES AT THE ROYAL SHOW, ADELAIDE, 1932

ARRIVED !!

SKIMMING BOWL, semigyroscopic.
BOWL SPINDLE, with improved conveyor.
NECK BEARING, with spiral spring cushion.
GEARING, new Automatic type. No springs or pins to handle.
OIL SUMP protected against milk or water.
SPEED INDICATOR.
FRAME beautifully enamelled, and
TINWARE heavily tinned.

Bigger sizes fitted with **BALL-BEARING SPINDLE**, eliminating neck bearing and reducing **OILING TO ONCE A YEAR**.

Write us for our Easy Terms and Allowance on old Separators.

30 DAYS' FREE TRIAL WILL ENABLE YOU TO TEST IT IN YOUR OWN DAIRY.

The Domo Separator Company
OFF WAYMOUTH STREET (Opposite "Advertiser")

Sultanas are selling at 10d. per lb. in the mallee, and 11lbs. at 10d. per lb. would cost 9s. 2d. So on the 11lbs. there is a save of 3s. 2d. As I only use the simple caustic dip—no olive oil or potash, as is used in the standard regulation dip for fruit for export—the cost of ingredients is only a matter of a couple of pence. The plain caustic-dipped sun-dried fruit is darker in color than the shade-dried fruit used for export, but there is a distinct difference in the flavor of the two, the sun-rayed fruit having a nice, rich flavor of its own.

For dipping, I use a petrol tin with a wire handle, and well-perforated sides and bottom. Care must be taken not to overcrowd the tin, so that the fruit may be properly dipped. All large tight bunches should be cut into smaller ones. The dip is as follows:—

To Dip Raisins.—12galls. water to 1lb. caustic soda. At 200 degrees dip the fruit just $1\frac{1}{2}$ seconds, or just in and out.

To Dip Sultanas.—30galls. water to 1lb. caustic soda. At 196 degrees drain and spread on wire netting racks or trays. Wooden trays dry them well also, but, if used, turn them about the third day, and they will soon dry. The length of time depends greatly on the weather. You can easily test them by squeezing one, and if moisture is there, they are not ready.

The quantity of the dip may be halved, or quartered, according to quantity of grapes dipped. I generally dip two to three cases, and use a quarter quantity of the dip, which is about half of a 16-gallon copper full.

Currents.—I just hang up to dry. If a glazed finish is liked, it can be obtained by dipping the bunches into the following mixture:— $\frac{1}{2}$ cup sugar, 1 cup water boiled for $\frac{1}{2}$ hour, but they take much longer to dry this way.

Dipping Prunes and Plums.—A stronger and boiling lye is needed. Dissolve caustic at the rate of 1lb. to 8galls. to 12galls. of water. The fruit is dipped for a period varying with the strength of the dip. If the stronger is used (1-8) the fruit should be submerged from 5 to 10 seconds; (1-12) the weaker should be submerged from 15 to 20 seconds. If the lye is too hot or too strong, or the fruits subjected to too long a submergence, they will burst when turned out on the trays. If perfectly dipped, the skins turn brown, and do not split after the lye has dried off them. During the drying process I do not bring the fruit indoors, unless it is wet weather. I just cover them well to keep off the night moisture, and uncover first thing in the morning. The fruit should never be allowed to become damp.

A FEW RECIPES FOR USING COLD MEAT.

(By Mrs. A. W. WELDEN, Parilla.)

Babotie.—1 onion, 1 cupful milk, 1 thick slice of bread, 2 eggs, any sort of minced meat, 1 small teaspoonful of curry powder, small piece of butter, pepper and salt. Soak the bread in some of the milk, fry the onion after cutting it up small, beat the eggs, and add the remainder of the milk. Mix these ingredients well together, and add minced meat, curry powder, butter, salt and pepper. Rub a pie-dish with the lemon or some vinegar, put in the mixture, and bake for 1 hour in a hot oven.

Lamb Souffle.— $\frac{1}{2}$ lb. cold cooked mutton or lamb, 1oz. butter, 1oz. flour, $\frac{1}{2}$ pint stock, 1 teaspoon chopped parsley, 1 tablespoon of tomato sauce, 2 eggs. Trim away all skin and fat, and pass meat through sieve twice, to make very fine. Melt butter in a saucepan. Stir in the flour smoothly, add stock, and stir until it boils. Put in the meat, parsley, tomato sauce, and season to taste. Take off fire, and let it cool a little. Stir thoroughly in the yolks of eggs, and lightly fold in the stiffly whipped white of eggs through the mixture. Put into a buttered pie-dish, shake a few bread crumbs over the top, and bake 10 to 15 minutes.

Macaroni Pie.—Take about $\frac{1}{2}$ lb. of any kind of cooked meat (minced), add pepper, salt, a little Worcester sauce, an onion cup up small, and 1 teacup of stock; place this mixture in well-buttered piedish, fill up with well-cooked macaroni, strew the top with grated cheese and dabs of butter, and bake for an hour.

Minced Meat Mould.—Mince very finely about 1 lb. of cooked meat, add pepper, salt, and grated nutmeg to taste. Beat 2 eggs well, and add $\frac{1}{2}$ pint milk. Mix all well together, put into basin, and steam about $\frac{1}{2}$ hour.

EYRE'S PENINSULA (CENTRAL).

[Minnipa, October 6th, 1933.]

WOOL AND ITS USES.

(By Mrs. CHILMAN, Warramboo.)

During the past 3 or 4 years prices of wool and sheepskins have been so low that it has been a golden opportunity for anyone who feels inclined to collect and clean wool for home use that would otherwise be wasted. At the present time prospects are a little brighter as regards the wool market, but even in normal times, when prices are fairly good and first-class sheepskins are considered too valuable to be used at home, there is often a certain amount of wool that can be collected without loss. For instance, if weevils get into a skin, which sometimes happens, in spite of all precautions, that skin is not worth sending to market, although quite good for home use. Sometimes after a sheep has been attacked by flies, the wool breaks and falls off; the whole fleece can be pulled off carefully, and this wool has no market value at all, yet some of the nicest and most easily cleaned wool I have handled was procured in this way. Then, at shearing time there are many odd pieces that are sold for so little that it is really more profitable to clean them and use for filling mattresses, pillows, cushions, &c.

Wool can be scoured and cleaned either on the skin or it may be shorn off first and washed loose. In either case, the first essential is an abundance of good soapsuds. In cleaning a complete skin it is best to divide it first into convenient sized pieces. The water should not be too hot, just right for the hands, and changed frequently. Six or eight waters are necessary to get it really clean, the last two being clear water. It is necessary to remove all traces of soap before drying. The pieces can be pegged on the line to dry, afterwards shorn with sheep shears. Washing the loose wool is a little more tedious, and I have found an old stretcher the best means of drying loose wool. Spread out on the wire mattress, and cover with wire netting to prevent blowing away.

Then there is the question of utilising the skin as well as the wool. This is a little more difficult. For this purpose it is better to use skins with very short staple; a lamb's skin, about 8 months, is ideal, or a recently-shorn sheep. Miss Campbell's method, which she procured from a Rundle Street furrier, began by soaking the skin 2 or 3 days in bran water to loosen the dirt, afterwards soaking again in a brine solution of salt, saltpetre, and alum; but fairly good results may be had by first washing the skin in the ordinary way, and partly drying, but before it becomes quite dry and stiff, nail out flat on a large box or board, and rub well with equal parts of salt, saltpetre, and alum. Rub thoroughly with a brick or stone, and repeat every day, if possible, for a week or more. The more it is rubbed and worked the more pliable and soft it will be. Skins treated in this way may be joined together to form a large mat for the floor, and can be successfully dyed any desired color. Smaller pieces can be used up in quite a number of useful ways.

Mrs. Chilman exhibited many specimens illustrating the uses of wool.

AGRICULTURAL BUREAU CONFERENCES.

Members of Women's Branches in the Pinnaroo District held a Conference at Parilla on September 26th, when Miss Colwill presided over a good attendance of local members and visitors. Papers were read as follows:—"Cultivation of Dahlias" (Miss Colwill, Parilla); "Cold Meat Recipes" (Mrs. A. W. Welden, Parilla); "Fruit Drying in the Home" (Mrs. Foale, Parilla); "Jam and Jelly Making" (Mrs. Bonnin, Pinnaroo); "The Vegetable Garden" (Mrs. Atze, Pinnaroo); "Pastry Making" (Mrs. C. Napper, Parilla Well); "Puff Pastry" (Mrs. C. Holmes, Parilla Well); "Home Nursing" (Mrs. Fisk, Pinnaroo); "Wholemeal" (Miss O'Loughlin, Pinnaroo).

In the evening Miss E. Campbell (Inspector Domestic Arts, Education Department) gave an address and demonstration on "Dressmaking."

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

River Murray Swamp Areas, at Murray Bridge, Thursday, February 15th, F. S. Burr (Secretary).

Lower North, at Riverton, Thursday, February 22nd, O. E. Longbottom (Secretary).

Yorke Peninsula, at Port Victoria (Wauraltee Branch), Wednesday, March 7th, M. Newbold (Secretary).

South-East (Upper), at Wolseley, Wednesday, March 21st, E. W. Sharrad (Secretary).

South-East (Lower), at Tantanoola, Wednesday, April 11th, H. M. Kennedy (Secretary).

Dawyang, at Milang, Wednesday, May 9th, L. E. Yelland (Secretary).

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Seed Wheat from Turretfield.

Mr. R. C. Scott (Supervisor of Experimental Work) reports very satisfactory sales of seed wheat from the Turretfield Farm. Ample stocks of Sultan, Gallipoli, and Federation, and limited supplies of Nabawa, Waratah, Sword, and Ranees are still on hand. Price 3s. 4d. per bushel on trucks Sandy Creek. Intending purchasers should lodge their orders early, with the Manager, Turretfield Farm, Roredale.

Crossbred v. Pure-Bred Dairy Cattle.

At the December meeting of the Sutherlands Branch of the Agricultural Bureau one of the members read a paper, "Dairying in the Sutherlands District," in the course of which the writer expressed the opinion that a cross between the Friesian and Holstein or any other two milking breeds would be of advantage over the pure-bred animal under conditions bordering on "Goyder's Rainfall Line." During the discussion that followed a member stated that the crossing of two strains within a breed would, in some instances, be a dangerous course, and expressed the definite opinion that better results would be obtained from the pure-bred animal. Many of the members present questioned the hardiness of the pure-bred, and held the view that these cows would not do well under such rigorous conditions. It was thought that a cross would be hardier, and therefore give better results in the long run.

The Chief Dairy Instructor (Mr. H. B. Barlow), who was asked to express an opinion on this subject said:—

Since the Friesian and Holstein are to all intents and purposes identically the same cattle—previously known as Holstein Friesian in Australia—this suggested "cross" would really result in breeding pure animals, provided both the male and female were registered. There are now no Holstein Friesians in Australia, as they are all registered in the Friesian Herd Book.

The suggestion that crossbred animals are more hardy than pure breeds is explained by what is known as *hybrid vigor*. It has long been recognised that crosses between different strains and varieties of races of animals produce very vigorous progeny. A very familiar, though extreme example, is the mule.

Although the hybrid vigor is often noticeable in crossbred dairy stock, it is usually only indicated by an ability to live under severe conditions, and not by any

“Now take the case of H. & D. M^cRae . . .”

These big Sydney Cartage Contractors say:

“Perdriau created great savings, cutting down tyre repairs and replacements and keeping trucks continually on road. . . Our strict time schedule demands best tyres procurable—Perdriau more than fills that role. Our fleet is Perdriau-shod for service, value and economy.”

Double toughened by a special process, the Perdriau tread saves money by slower wear and longer mileage. Perdriau means real economy at the new reduced prices.

Perdriau

**DOUBLE TOUGH
TRUCK TYRES**

greater ability to produce milk in excess of the quantity you would expect a pure-bred animal of the same size and age to produce under the same conditions. Probably there would be a tendency for the crossbred to produce less milk if possible, but appear more robust. It is suggested that since it is a fact that cows can only produce milk in proportion to the amount and kind of food they obtain, the question of semi-starvation should not be a consideration. If conditions such as this must pertain, then it would probably be more profitable to keep goats, which can notoriously exist under very harsh conditions.

If the conditions are as harsh as is suggested it is doubtful whether any cows, pure or crossbred, would give satisfactory results, but if sufficient food is made available, I am inclined to think that the average pure-bred animal will quite hold her own from a production point of view with the average crossbred. It is not always a sound argument to compare the production ability of a good crossbred animal, of which there are many, with the production of a mediocre pure-bred animal, which are more prevalent than they should be.

Egg-laying Competition at Parafield Poultry Station.

The Minister of Agriculture, Hon. A. P. Blesing, M.L.C., has authorised an Egg Laying Competition, commencing at Parafield Poultry Station on April 1st. Recognising the necessity for improving the standard of the poultry stock of the State the Government is increasing the accommodation at Parafield to 500 Single Test Pens. This test offers breeders an excellent opportunity of having their stock tested under official supervision. The weight of every egg laid during the currency of the test will be recorded and will be available at the conclusion of the test to competitors. With the progress of the export trade, which brings our producers into competition with practically every egg producing country in the world, the necessity for maintaining the standard of our stock is being very fully realised. The Single Test method gives an accurate record of the performances of the birds over a period of 12 months, and gives breeders an excellent foundation for the breeding stock.

Full particulars can be obtained from the Government Poultry Expert, Box 901E, Adelaide.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Mortana reports mare with occasional cough, good appetite, large hard swelling on chest.

Reply—Give the following treatment:—(1) Starve for 18 hours. (2) At the end of that time give the following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 4 tablespoons; shake thoroughly before giving. (3) Subsequently feed on good quality chaff, bran, and crushed oats. (4) Give 1 tablespoon of Fowler's solution of arsenic in a small damped feed night and morning for 14 days. Report progress in 21 days.

Black Rock Agricultural Bureau asks—(1) Correct way to feed cocky chaff. (2) Sheep with sores on shoulders. (3) Correct method of branding sheep that already carry one brand.

Replies—(1) Cocky chaff has a low feeding value and is very deficient in mineral matter. It should therefore be used in conjunction with oats and a mineral mixture. If oats are used, there is no necessity to buy bran or pollard. Bran is higher in mineral matter than pollard. A mineral mixture as suggested below should be fed to the cows:—Dicalcic phosphate, 60 parts; coarse salt (35-37% P₂O₅), 40 parts. For the average milking cow mix 4ozs. of the mixture in the feed daily. (2) Clip wool away from wound, wash daily with salt solution (teaspoonful of salt to the pint of water), and subsequently swab on the following mixture:—Creosote, 1 part; oil of

turpentine, 6 parts; raw linseed oil, 20 parts. (3) A sheepowner obtaining sheep which are already branded on his position should not use his registered brand, as the resulting combination may produce the brand of another person; also, blotch branding might easily be caused. The alternative is to use a numeral. The figures 2 to 9 may be used as flock marks on any part of the sheep by the owner of a registered brand only: Provided that *only one* of such numerals be used on any one sheep, and the size not to exceed 4in. in height.

Greenock has 12-year-old draught gelding, eats ravenously, saliva flecked with blood. Raises the head and arches the neck.

Reply—Have the teeth examined and attended to if necessary (the quidding of half masticated food is a sign of defective teeth). Give the horse a *little long hay before each feed* of chaff. Further, feed the chaff damped. Two tablespoons of Fowler's solution of arsenic in a small damped feed should be given once daily for 14 days.

Wisanger, Kangaroo Island, reports horse 15 years old, frogs of both front feet deformed. Deep holes alongside of frog, which is festered.

Reply—The complaint is probably thrush, which is an inflammation in the tissues underlying the frog. Try the following treatment:—Cut away all ragged and overgrown frog, so that any matter (pus) and discharges can escape, but do not remove good sound frog tissues. Apply the following mixture:—Oil of creosote, 2 drams; methylated spirits, 2ozs.; shake well. Pour a little into crevices and cleft of frog, and then plug with cotton wool or tow. Repeat treatment daily until discharge ceases. It is essential that the mare be kept on a good dry bed or floor.

Pinnaroo has calves lost use of front legs; hind legs stiff; and frothing from nose.

Reply—The paralysis is very probably due to defective nutrition (mineral or vitamin). It is doubtful if it will pay to treat the calves as recovery is very slow, but should you wish to do so, they should be put on to fresh whole milk. A tablespoon of cod

Port Adelaide and Wallaroo.

liver oil should be given twice daily. To give this, put in bottom of bucket and gradually stir in the ration of milk. Should you wish to rear any further calves, a tablespoonful of cod liver oil should be given daily in the milk.

Warrambo reports epidemic of "pink-eye" in flock of sheep.

Reply—Some sheep men let the disease take its course, but the following treatment is advised:—(1) Affected cases should be separated from healthy sheep. (2) If possible, put them in a small paddock, where there is shade and water. Hand-feeding is advisable. (3) Put a few drops of a 4 per cent. solution of zinc sulphate in eyes daily. The disease is highly infectious; be careful not to spread infection by handling healthy sheep after affected ones. The hands should be disinfected. The disease is usually introduced with bought sheep, and is due to a germ.

Merghiny reports horses with cough and discharge from nostrils.

Reply—The condition may be influenza or a mild form of strangles. The following treatment is suggested:—(1) Isolate all affected horses. (2) Put on to good quality chaff, bran, and a little crushed oats. (3) Give each horse 1 teaspoon of powdered nux nomica night and morning for 14 days. To give, mix with treacle and smear well back on the tongue. (4) If any green lucerne is available, a daily ration would help them considerably. Horses with a cough and a discharge should have the head steamed daily with eucalyptus.

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. GEO. QUINN, Chief Horticultural Instructor.]

Defective Gordo Fruit Bunches.

A grower of large quantities of Muscat Gordo grapes in one of the irrigated areas sent three samples of bunches and berries of Gordo vines to Mr. G. Quinn (Chief Horticultural Instructor) with a request as to the cause of the non-setting of the berries of some bunches, and drying off of fruits on others, and the parboiled condition of others found lying on the sand in the sun under other vines.

He states his crop was much reduced each season by these defects, which he attributed to the Oidium fungus.

Mr. Quinn replied as follows:—

(1) I can detect no evidence of injury by the Oidium (Powdery Mildew) fungus on these berries or stalks. I know there is, amongst the older settlers on the Murray, a suspicion that this non-setting of the Gordo fruits is caused by an early attack of Oidium, but, if seeing is believing, I am an unbeliever, as I have never yet found visible evidences to that effect on similar specimens to those you submit. There is evidence on the inflorescence where the sprigs of red dried berries are located, of the presence of a caterpillar—I should say the active small green larva of the *Cacoecia postvittana*, or Light Brown Apple Moth, a native leaf rolling caterpillar which in the spring and early summer attacks all sorts of plants—roses, apples, and grapevines in particular, when these latter are just setting. It bites the stalks of the branchlets, eating the green outer bark, and webs up the embryo berries which, being thus cut off from nourishment, die early. This pest, as a rule, disappears with the advent of settled hot weather, but during a cool summer goes on breeding and feeding on the bark of the now growing bunches. In a vineyard little can be done, excepting it be possible to go over the vines and pull the newly set bunches free from leaves and tendrils which crowd them and give shelter to the pest. This, combined with sulphuring which may incommode the caterpillars, as well as prevent a possible attack of Oidium.

(2) These berries represent fruits which have been separated from the bunch and lying on the hot sand have been simply parboiled. As you know, prior to the stage of developing sugar, the Gordo berries are very readily reduced to this condition, and eventually, as they dry out, become hard and red. Similar berries were contained in No. 1 sample in both stages of desiccation.

(3) This wilting of the distal end of the bunch (inflorescence) would appear to be possibly caused by two factors:—(1) In the first place, as it hangs down it is in a subordinate position for receiving sap—i.e., sap does not flow down below a horizontal position equally well with its upward movement in more vertical parts of plants. If the vines are beginning to become sluggish through the soil drying out between irrigations the fruits are robbed by the leaves, and it may be assumed the lowest portion of the bunch most—owing to the above rule. (2) The heat reflected or radiated from the sand may cause this, more particularly if the lower point of the bunch is near to the ground surface. There is no evidence of insect injury on the stalk of this specimen.

PARAFIELD POULTRY STATION.

**Free on Rail,
Salisbury.**

**DELIVERY.—CHICKS—February and March.
EGGS—January and February.**

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

The general proposition of the scattered or tardy setting of Gordo berries being so general would appear to indicate a lack of cross pollination, and an evidence of lack of potency in the pollen produced in the flowers of the Gordo. This characteristic is very marked in the closely allied variety, Muscat of Alexandria, which is regularly cross pollinated by hand in glasshouse-grown vineries. The paw or tail of a rabbit or hare is rubbed over the flower bunches of some other sort flowering at the same time, and then rubbed up and down the flowering bunches of the Muscat of Alexandria.

This cannot be done in the open field, but a good sulphuring at the time the caps are falling from the flowers is claimed by French vigneron to stimulate setting of those sorts of wine grapes which have similar characteristics.

The French vigneron call this failure to set "Coulure," and they definitely claim that sulphuring lessens it, but cannot say whether it is because it prevents the attacks of *Oidium* or perhaps other unrecognised fungi on the blossoms, or merely that the puffing of a current of sulphur-laden air through the inflorescence mechanically promotes distribution of the pollen produced by the Gordo blossoms.

Pruning Orange and Lemon Trees.

Replying to the Secretary of the Laura Bay Branch of the Agricultural Bureau who asked, "Is it necessary to prune citrus trees?" Mr. G. Quinn (Chief Horticultural Instructor) says:—These trees require attention when small, chiefly to make sure that the principal branches do not grow across each other or across the centre of the tree. This is to give balance to the framework. As they grow larger, some thinning may become necessary to prevent the inner parts of the framework being crowded. As a rule, this crowding results in much dead twiggy wood accumulating on the limbs inside of the tree.

It is not desirable to prune a citrus tree so as to form a hollow vase shape—as is done with most deciduous kinds of fruit trees—but to aim at maintaining a dome-like canopy of leaves right over the framework, almost as the fabric of an umbrella covers the framework of that useful article. The leaves are required to act as a shade to deflect the strongest sun heat, as well as to do their share in the metabolic processes necessary to the well-being and growth of the plant.

When the lower branches are, by the natural extension of those above them, forced to a pendulous position and touching the soil it is well to shorten back their extremities either wholly or in part. In practice this usually first takes the form of shortening them back to where a small growth turns upwards but subsequently it may be necessary to remove them so as to lift the fruit and leaves 1 ft. or more above the soil.

The object of this procedure is to gradually lengthen the main stem as the lower limbs are removed but generally this action is spread over several years, thus avoiding at all times unnecessarily exposing the bark of the trunk and main limbs to the direct rays of the summer sun.

When the citrus trees reach a fruitful and mature stature, the canopy of foliage becomes less dense on the top, and then small lateral shoots are allowed to develop on the inside framework of the tree where they often produce the most perfect fruits.

There is no set time for pruning citrus trees, excepting that any limbs or boughs which permit a direct entry of sunlight should be cut away in spring or early summer, when the sap is flowing freely and new growths may close over the gaps with protecting foliage before the sun exercises extreme power.

Dead brush wood may be cut out at any period when the owner can find time to do the work. Large cuts made in the removal of limbs should be smoothened with a knife, and painted over the exposed woody part with thick pasty lead paint to facilitate a safe and healthy growth of covering tissue.

Tested and Proved

for

VACUUM OIL COMPANY PTY. LTD.

NATURAL AND FEDERAL DISABILITIES OF SOUTH AUSTRALIA, VIEWED AS AN ESSENTIALLY AGRARIAN STATE.

[By ARTHUR J. PERKINS, Director of Agriculture.]

EVIDENCE GIVEN AT ADELAIDE BEFORE THE COMMONWEALTH GRANTS COMMISSION, DECEMBER, 1933.

South Australia is without exploitable Coal deposits, and it follows that industries, social services involving the use of Power, Rail transport, and incidentally costs of rural production, are in some degree controlled by those from whom Coal is procured; nor has it permanent running waters from which Power might be economically derived. Again, apart from Copper deposits which at present are lying dormant, Gypsum, Salt, and limited Iron Ore deposits, it lacks mineral resources of any great importance. South Australia has no natural forests of appreciable commercial value, and its only permanent water-course is the lower reaches of the River Murray. The logical corollary to these natural disabilities is a present-day lack of population in proportion to territory effectively occupied, and it must be admitted that natural conditions, quite as much as the Federal tie, have compelled South Australia to develop, in the main, along agricultural and pastoral lines. But apart from these natural disadvantages, the cumulative pressure of 30 years' Federal fiscal policy upon rural production in South Australia has been very severe. The avowed aim of this policy has been industrial self-sufficiency of a handful of people, and it has operated very much to the disadvantage of South Australia, the solvency of which as a State is ultimately dependent upon its ability to export rural produce at a profit. I shall support this statement by the following considerations:—

In the first place, it must be fairly obvious that a community depending so largely upon rural output for home expenditure and commitments abroad must be economically able to face World competition and to accept World prices, coupled with corresponding parity for home consumption. In other words, without loss to itself it must be able to sell in the cheapest markets. In such circumstances, its solvency would appear to rest upon corresponding ability of its primary producers to buy in the cheapest markets; nor is this possible except under the incidence of a revenue or low tariff policy. Unfortunately, from the standpoint of South Australia, and that of other rural States, Federal Fiscal policy has, from its inception, been one of high Tariffs, the height of which has progressively risen from period to period, culminating in the all but prohibitive rates of 1930.

What have been the outstanding effects of this policy? It has assisted to build up two huge cities—Sydney and Melbourne—and in the process it has forced up costs of rural production to such an extent that it is becoming increasingly difficult to dispose of Australian rural produce at a profit to producers on the markets of the World.

Between 1901 and 1931 the population of Sydney rose from 478,900 to 1,256,230, and that of Melbourne from 494,129 to 1,030,750, that is to say, increases of 157 per cent. and 109 per cent. respectively over a period of 30 years.

Again, the value of the yearly output of the factories of New South Wales and Victoria rose between 1907 and 1929—a period of 22 years—from £66,924,646 to £313,196,038, representing an aggregate increase in value of £246,271,392, or 368 per cent. above 1907 values.

It would appear, therefore, that the factories of our two large cities have flourished exceedingly behind the High Tariff Wall of Federal Policy, but unfortunately, apart from articles of Primary Production, such as Butter, Cheese, Flour, &c., their enormous and costly output has not proved exportable, and has in the main been reserved for Australian Home consumption. And however much their own private interests may have been injured thereby, Australian consumers and users have been compelled to purchase these locally manufactured articles at prices considerably in excess of world parity, with crippling results upon general costs of production. In this connection, the following figures from the Commonwealth Year Book are illuminating. The total value of Commonwealth Exports for 1930-31 is given as £101,402,814, of which £99,139,484 represented Primary Produce and £2,263,330 manufactured articles other than primary products, or 2.2 per cent of the total only. Hence, the infinitesimal value of locally manufactured articles, other than primary produce, from the standpoint of our commitments abroad should be fairly obvious.

The immediate effects of high tariffs would seem, therefore, to be that those on the wrong side of the Tariff Wall are forced to pay considerably more than World parity for articles manufactured in their midst, and under a drag-net Tariff of the type we have recently experienced the cumulative result is an inevitable all-round increase in the cost of living, which in its turn leads sympathetically to progressive increases in the cost of wages. The latter then become responsible for further increases in the necessities of life and industry generally, and are ultimately reflected in progressively increasing costs of rural production, upon which rests precariously at the present time the whole superstructure of the State.

In the years that immediately succeeded the War, the insidious rise in costs of rural production was to some extent masked by a brief period of unusually high prices for rural produce. This period has now come to an abrupt end, and I hold firmly to the belief that an important, if not the main factor behind the crisis through which South Australia is passing, and indeed, to a less degree, the Commonwealth as a whole, is the fact that World prices for primary products no longer balance our artificially swollen costs of production. This unfortunate position is attributable both directly and indirectly to a relentless policy of prohibitive tariffs; and since as a State we have not the advantages of the accumulated wealth of locally protected manufactures, and have to pay toll to the industrialised States for the necessities of life and industry, the Federal Government cannot, in my opinion, escape the responsibility for a position very largely of its own creation.

The time at my disposal does not permit of a detailed examination into Costs of Production of the various phases of rural activity, and I shall have to content myself with a few typical examples with which I am familiar.

Wheat, because of its ready adaptability to our conditions of climate and soil—and, prior to Federation, it could have been added to our economic conditions as well—Wheat looms very large in the history of the State. Indeed, together with Wool, we may be said to owe to it whatever development we have hitherto attained to. It follows, therefore, that anything relating to its Costs of Production is of paramount importance to the State, and indeed to a less degree to the Commonwealth as a whole. Unfortunately the determination of a mean figure applicable to the State as a whole is an exceedingly difficult, if not impossible, proposition; these costs must necessarily vary from district to district, from farm to farm, and even from season to season on one and the same farm. Nevertheless, in existing circumstances, I do not believe that anyone could be found with any real knowledge of the question who would maintain that 2s. per bushel and less on the farm could possibly meet current costs of production. I have

been responsible for a Government Farm (Turretfield) which for 10 successive years had been run from its own revenues without the assistance of a Government grant, and during the course of which all expenditure was submitted to detailed analysis. I append as a contribution to the subject itemised statements of actual Costs of Production of Wheat (1) at Turretfield for the three-year period closing on June 30th, 1932, and (2) on a private Mallee Farm, the accounts of which were kept by the Department of Agriculture over the same period.

Balance of expenditure	2 8 6	2 6	61·0	1 9 0	1 9	59·5
Totals	3 19 5	4 1	100·0	2 8 8	2 11	100·0
Mean yields per acre	19·20 Bushels.			16·92 Bushels.		

We have here two authentic examples of the Costs of Growing Wheat under existing South Australian conditions: one is representative of the older settled, heavy soil, Central and Lower North Divisions of the State, and the other of the more recently settled lighter soil Mallee Lands. As might have been expected, wheat can be grown at lower costs on the cheaper and lighter Mallee lands than in the older settled portions of the State. Attention is drawn to the fact, however, that even in the Mallee, costs on the farm are 2s. 11d. a bushel, which correspond to 3s. 6d. on truck Port Adelaide, as compared with 2s. 6d. on trucks only, which is at present being offered. Moreover, the mean yield of the Mallee Farm under consideration, namely, 16.92bush., is considerably higher than that.

of the Murray Mallee Division as a whole, namely, about 8bush. to the acre for crops sown on fallow land: if subject to correction for reduced harvest costs, we assumed similar expenditure per acre for the Murray Mallee Division as a whole, we would find that a mean yield of 8bush. per acre would involve costs in the neighborhood of 5s. per acre, that is to say, twice as much as is being offered at outports to-day.

Finally, and apart altogether from the direct influence of high cost of living upon the farmer himself, I shall add that most of the items included in the Costs of Production of Wheat admit of appreciable reductions under a policy of Low Tariffs. Indeed, I am prepared to go as far as to say that if Port Adelaide were a free port, even Wheat at 2s. a Bushel would not necessarily prove a losing proposition.

In 1913 I had occasion to put on record current values for farm machinery, essential farm material, tools, &c. These values have been summarised below in contrast with corresponding 1933 values:—

	1913.	1933.	Per- centages increases.
	£ s. d.	£ s. d.	%
Essential farm machinery	518 17 0	638 13 6	23·1
Farm harness	21 16 6	30 9 5	39·6
Miscellaneous tools.....	3 9 3	5 17 5	69·6
Other materials essential to wheat growing.....	91 13 0	100 13 1	9·8
Totals	£635 16 0	£775 13 5	22·0

In considering these figures we must not overlook the fact that the original 1913 Total, namely, £635 16s., representing current purchases of farmers, was already a protectionist total that no farmer should be called upon to bear: this total rose to £901 in 1925; fell to £826 19s. 4d. in 1930, and to £775 13s. 5d. in 1933, which is still 22 per cent. higher than the original 1913 protectionist total. Figures such as these involve heavy Interest and Depreciation charges, which tend to render the growing of Wheat exceedingly costly and unprofitable whenever climatic conditions reduce yields to low levels, or World Economic conditions have a corresponding effect upon prices.

How heavily interest and depreciation charges weigh upon the farmer, and more particularly upon the farmer handling relatively small areas, was made clear in a recent inquiry which I made into Capital invested in South Australian Wheat Farming. Figures given below summarise the position, apart from interest on land or rent.

Estimated Mean Interest and Depreciation on Improvements and Working Plant on Farms of Varying Dimensions.

	Mean Areas.	Assumed Mean Yield per acre.	Mean Interest and Depreciation per bushel.
	Acres.	Bushels.	s. d.
Very small farms	287	18·87	2 2
Small farms	633	17·78	2 0
Average farms	988	14·05	1 11
Large farms	1,651	11·86	1 10
Very large farms	3,077	10·00	1 9

The above figures are based upon an inquiry into the position of 129 South Australian Wheat Farms. It will be observed that interest and depreciation charges on improvements and working plant are practically equivalent to current prices of Wheat on the farm. The uneconomic height to which these charges have attained is one of the consequences of a high tariff policy.

In 1927 I had occasion to keep the accounts of a prominent Dairyman situated on the River Murray Reclaimed Swamp Lands, and notwithstanding the fact that for the year his Herd averaged more than 1,000 galls. of Milk for every cow in the herd, the inclusive costs of the milk produced were a shade under 9½d. per gallon.

The recent attitude of the Belgian Government towards exportable primary products in which many South Australian producers are vitally interested is surely a reminder that a policy of economic self-sufficiency, which has brought 130 million Americans to the brink of ruin is not likely to succeed in Australia; we cannot expect others to purchase our goods if we refuse to take theirs in exchange. Until the inevitable crash comes this particular aspect of the question may not interest our manufacturers of unexportable commodities, but what in the meanwhile are the primary-producing States of the Commonwealth to do?

Another consequence of our National policy, which hits primary producers heavily, is that so long as we refuse to balance exports of primary produce by corresponding imports, cargo vessels must reach Australia in ballast, and outward freights must be correspondingly higher. This means that our producers have been compelled to accept lower export parity for their goods than would have been the case had our National policy been more in keeping with the natural requirements of an Agrarian State.

I recognise freely that South Australia is not the only State dependent upon rural output for continued prosperity; and although this dependence may not be quite as great as our own, the Commonwealth might perhaps justly be described as a federation of rural States with two highly industrialised Cities. But unfortunately even in this matter of rural production we have special difficulties of our own which tend to place South Australia at a disadvantage relatively to the better endowed Sister States, and to these difficulties I propose now drawing attention.

It is well recognised that over the bulk of Australia, Rainfall and its seasonal distribution dominate Crop Production and the relative abundance of grass or Livestock-carrying capacity of the land. In this connection, out of territory 380,070 square miles in area, 310,660 square miles or 81.7 per cent. of South Australia receive less than 10in. of yearly rainfall, and lie therefore outside normal cropping areas. Corresponding percentages for land outside the 10in. rainfall line for Sister States are as follows:—Western Australia, 49.9 per cent.; New South Wales, 15.7 per cent.; Queensland, 12 per cent.; whilst in Victoria and Tasmania a rainfall in excess of 10in. is received by each State throughout their respective territories. It must be clear, therefore, that in South Australia the available cropping area is very much restricted by unfavorable rainfall conditions.

Again, of the country receiving in South Australia 10in. and more of rain, a limited proportion only is suitable for agricultural operations. In this connection it is estimated that not more than 15,000,000 acres can be described as arable land, that is to say, 33.8 per cent. only of the land receiving 10in. and more of rain, and 6.4 per cent. only of South Australia's total territory.

Moreover, of our arable area in the neighborhood of 10,000,000 acres, or two-thirds of the total is "Mallee Land," and as such of relatively low natural fertility. It is this fact that tends to keep our mean crop yields at a relatively low level, and to make it extremely difficult for at least 50 per cent. of our farmers to face artificially raised costs of production, and their personal straits are reflected in the financial difficulties of the State.

Another serious difficulty is the absence of good underground water supplies for Livestock and other purposes over the greater part of South Australia. This has rendered necessary the building up of costly reservoirs with attendant reticulation systems to meet the needs of an extremely scattered population, and the building and upkeep of these national works has been a heavy burden on State finances.

Our pastures and our hot dry summers do not lend themselves generally to dairying, except with the costly assistance of hand-feeding over six months of the year, and we have usually found ourselves compelled to import butter for home consumption over portion of the year. This disability has hitherto hampered our attempts at closer settlement. Apart from the very limited areas of Reclaimed Murray Swamps and portions of our Hills Districts, the only important tract of country likely to prove suitable for Dairying is situated in the South-Eastern Statistical Division of the State. Unfortunately, much of the latter country is usually under water in Winter, and has already involved the State in heavy expenditure for drainage, and is likely to cost a good deal more before the work can be completed.

It is true that we possess important tracts of country admirably adapted to fruit and vine-growing, whether under irrigation or conditions of natural rainfall. Unfortunately, the Federal high tariff policy has forced up Costs of Production to such an extent that to-day it is no longer possible to market fruit and fruit products overseas to any great advantage. The uneviable position of the canned and dried fruit industries is a case in point. To these might be added the stagnation of the Olive Oil industry, which is barely able to face foreign competition on the home market, although admirably adapted to local conditions of climate and soil, and which prior to federation appeared to be full of promise for the State. But with the cost of mere picking in the neighborhood of £5 a ton, it is little wonder that Olive growing is looked at askance by would-be growers. And it is analogous reasons that prevent us from developing a profitable overseas trade in Pig Products.

Finally, our high Railway rates which are partly one of the consequences of the scattered nature of our land settlement and partly one of the consequences of a high tariff policy, are very burdensome upon local rural production. These rates are relatively heavier than in neighboring States as the following examples will show:—

	Wheat.		Superphosphate.	
	First 50 Miles. per bushel.	First 100 Miles per bushel.	First 50 Miles. per ton.	First 100 Miles. per ton.
	d.	d.	s. d.	s. d.
South Australia*	2.95	4.39	5 5	9 8
New South Wales	2.44	3.86	5 0	6 9
Victoria	2.14	3.29	3 8	5 7
Western Australia	2.65	3.51	3 3	4 1

*NOTE.—Since the beginning of the present season and until the end of June, 1934, rates payable by South Australian Farmers for wheat and super have been reduced by 20 per cent., namely:—

First 50 miles for wheat	2.36d. per bush.
First 100 miles for wheat	3.51d. per bush.
First 50 miles for super	4s. 4d. per ton
First 100 miles for super	7s. 9d. per ton

But in so far as the State is concerned, the position remains the same, since the State Treasury must pay the 20 per cent. to the credit of the Railways.

I understand that the warrantableness of some of the developmental expenditure incurred by the State within recent years has been questioned, and in particular expenditure incurred in the gradual development of Eyre Peninsula.

In the latter connection it is necessary to draw attention to the fact that 60 per cent. of the area of the State lies to the West of Port Augusta, including Eyre Peninsula and its Northern hinterland, and 40 per cent. only to the east of the Port, including the earlier settled portions of the State.

It seems to me unthinkable that any State could afford to leave idle more than 50 per cent. of its effective area, when it was known that a large proportion of this area was suitable for Sheep or Wheat, upon which the Eastern portion of the State had been effectively settled. Attention should be drawn to the fact that the greater part of the Peninsula was covered with Mallee or low scrub, and that the actual cost of clearing and development had fallen not upon the State, but upon the individual settler, and frequently to his eventual loss. Nor should it be forgotten that however good the quality of the soil, Mallee Blocks, reclaimed by individual settlers, cannot as a rule be expected to reach normal farming conditions until at least 10 years, and frequently more, from date of original settlement. Unfortunately, Settlers have been faced by a series of unfavorable seasons since early settlement, and the State has been compelled to supply them with special assistance to enable them to keep on the land. The position has been further complicated by the settlement of Returned Soldiers on the only available Crown Lands of the State, and many of them have unfortunately proved unsuitable settlers.

The main State developmental works on the Peninsula are represented by a narrow-gauge railway line and an attempt to provide water to the central areas from its Southern end. The expenditure involved was inevitable if the Peninsula was to be settled, and in my opinion with the eyes of land-hungry neighbors upon our sparsely-settled areas no State could afford not to attempt the settlement of more than one-half of its available area. It is probably true that public works on the Peninsula do not at present pay interest and are, therefore, a burden upon taxpayers of the eastern half of the State. But with a complete knowledge of the Peninsula and its conditions I am prepared to maintain that, given a fiscal policy more in keeping with the rural requirements of the Commonwealth than we have hitherto experienced, Eyre Peninsula should, in the course of time, be able to meet interest on any expenditure that may have been incurred on its behalf. I stated in evidence before an earlier Commission that between 1935 and 1940 the Peninsula should carry in the neighborhood of 1,500,000 acres of Wheat, from which 15,000,000 bush. might be expected, and that its flocks should expand to from 1,600,000 to 1,800,000 sheep. To these opinions I still adhere, with the addition that the Dairying and Poultry Industries are also capable of important development over this area. As a contribution towards my anticipations in this direction, I shall point out that already in 1931-32 Eyre Peninsula had about 1,137,000 acres under wheat, and a production of over 10½ million bushels.

The costliness of the River Murray settlements has also been criticised, and in some directions perhaps not without reason. Mistakes have no doubt been made, but could it have been otherwise in a national undertaking of this magnitude? Two factors have added very considerably to the costs incurred, namely:—

1. The hurried settlement of numerous Returned Soldiers anxious to resume normal civil life, which for sentimental reasons could not have been avoided; and
2. Direct and indirect influence of a high tariff policy.

I am of the opinion that in its attempts at settlement of Eyre Peninsula, and at development of the River Murray Irrigation areas, particularly in relation to the settlement of Returned Soldiers, South Australia has undertaken national

work of major importance, and that considering that the policy that has led to the enrichment of the industrial States has led to corresponding impoverishment of South Australia, it seems reasonable that the Commonwealth as a whole should assist this State to carry a burden which unfortunately it is no longer able to bear without outside assistance.

It is often stated that the countryside benefited from economic association with large centres of population, and whilst from the general viewpoint this is undoubtedly true, it cannot be said to apply to the association of essentially rural communities, such as South and Western Australia, with distant urban centres, such as Sydney and Melbourne, the home territories of which were amply adequate for the supply of all requirements. Unfortunately, the collection of Interstate statistics on the subject has been abandoned since 1909, and it is no longer possible to set out the actual position on the basis of exact figures. From inquiries that I have made, however, it would appear that the value of our Interstate exports of Horticultural Produce for the 12 months ending on June 30th, 1930, did not exceed £170,000, and consisted chiefly of oranges and tomatoes consigned to the Melbourne Market. Our Wines and Brandies, on the other hand, have undoubtedly benefited from Federation, and now have an Interstate export trade of a yearly value varying from £500,000 to £750,000. But this is a very small set-off to the value of the manufactured articles we are compelled by High Tariffs to receive from the industrialised States.

The Federal disabilities under which South Australia appears to me to labor may be summarised as follows:—

1. Natural conditions have made of South Australia an essentially rural State, and unfortunately she has been unequally yoked in a federation with two large States which have gradually expanded upon industrial lines.

2. Federation has checked the development of local industries, and in some cases obliterated them. It has raised the cost of necessities of life and industry, with corresponding increase in costs of rural production, upon which our economic life is wholly dependent. Natural conditions compel us to sell in the cheapest markets and artificial ones to buy in the dearest.

3. And to-day South Australia finds it almost impossible to market surplus agricultural produce overseas at a profit to producers and to the State.

4. The practical disappearance of taxable industrial wealth from the State has thrown the burden of taxation upon rural production and impoverished the State and its main producers.

5. Even as a rural State, South Australia suffers in comparison with its better-endowed neighbors. Over 81 per cent. of its territory lies outside the 10in. rainfall line, and no more than 6.4 per cent. of its total territory is suitable for agricultural operations. Moreover, the major portion of the land in cultivation is "Mallee" land, and therefore of relatively low natural fertility.

6. The absence of good underground water supplies has rendered necessary costly artificial supplies for both town and country, and has helped to inflate costs of rural production, both directly and indirectly.

7. Closer settlement has been hampered by Federal Fiscal Policy, with the result that we have been thrown back upon extensive farming and the normally low returns per acre which characterise this type of farming.

8. Forty per cent. of the territory of South Australia is carrying the burden of three national undertakings of major importance, in which the Commonwealth is intimately concerned, namely:—

- (a) The development of Eyre Peninsula, which may eventually claim the position of a separate State;
- (b) The opening up of the River Murray Irrigation Areas; and
- (c) The settlement of Returned Soldiers.

9. The limits of local taxation appear to have been reached, if not over-stepped, and to remedy the position in which we find ourselves, I know of no alternative but—

- (a) A radical change in Federal Fiscal Policy towards low tariffs for revenue only;
- (b) Substantial Federal grants enabling the State Government gradually to reduce local taxation, which eventually would be reflected in lower cost of rural production;
- (c) Secession which would restore to us our liberty of action and enable us to work out our destinies on our own lines.

I recognise that in ordinary circumstances my statement of our disabilities should end here, and that any addendum would be in the nature of an anti-climax. Quite recently, however, I happened to come across an article in *Nineteenth Century Magazine* entitled "A Policy for Central Europe." The article, which is by a former Minister of Agriculture of Czechoslovakia, is a reply to the suggestion that Europe should adopt a Federal Tariff Union. The position as pictured by Doctor Milan Hodza is so similar to our own that I take the liberty of adding a few extracts as an appendix to my personal statement:—

"If we imagine Pan-Europe as a Confederation with the tariff barriers raised, as a unitary customs area, then it is clear that Pan-Europe is not possible, and, even were it possible, that it could not be advantageous, and therefore not permanent. Europe is not an economic unity. West-Europe, predominantly industrial, has other economic interests than the agrarian States of Central Europe. West-Europe has a surplus output of industrial products, we have a surplus output of agricultural products, and therefore we must make a distinction between what would benefit the international Capital invested in West-European industry and what the farmer in Central Europe urgently needs . . .

"If Pan-Europe were to arise suddenly, sweeping away all the Tariff barriers, including the agricultural, we should be overwhelmed by the economic and financial power of West-European Industry. We should have all the disadvantages of a great customs area dominated by industry, and we should have neither the strength to resist nor the guarantee of an economic safeguard for agriculture. That would mean the pauperisation of agrarian States of Central Europe and the pauperisation of agrarian democracy itself. If the farmers of these States cannot safeguard their products, and the State cannot safeguard its small peasant landholders, that would mean that agrarian democracy would be shaken to its foundations in Central Europe, since the agrarian represents the only stable element. It would mean that the ground was cut away from under the feet of cultural development in Central Europe. We should be threatened by the danger of chaos which is to-day in the neighborhood of Soviet Russia, altogether unthinkable.

"That would be the effect of Pan-Europe as it is at present conceived organised from the standpoint of West-European capitalism and industrialism. It is for this reason that we must approach the question of international 'reapprochement' by progressing from the smaller problems to the greater, and not *vice versa*. Only in this way can Pan-Europe be made a reality, resting not on public manifestations of international enthusiasm, but on a real abolition of the economic friction between the different States."

There, it seems to me, speaks a man of far greater vision than the South and West Australian protagonists of Federation in the last century. We accepted Federation and unified customs without taking thought of our special agricultural interests, and now we are suffering for the lack of thought of the Fathers of Federation and the "public manifestations" of Federal "enthusiasm." It is much to be hoped that in common fairness, future generations will not be permanently penalised for the hastiness and lack of foresight of their ancestors.

MALLEE FARM COSTING.—FARM No. 1.

[By ARTHUR J. PERKINS, Director of Agriculture.]

PART I.—GENERAL.

1. INTRODUCTORY.

The farm under consideration is a private farm situated in the Murray Mallee division of the State, concerning which a preliminary Report was published in the February, May, June and July (1932) numbers of the *Journal of Agriculture*. This farm has been managed and worked by its owner, but its accounts have been kept by the Department of Agriculture for three successive seasons, namely—1929-30, 1930-31, and 1931-32; and it is on the mean results of these three seasons that the costing accounts have been based.

At the beginning of the opening season the local District Instructor (Mr. R. L. Griffiths) reported on this Farm as follows:—

“This farm is in a district with a 16-in. rainfall and is typical of large areas in the southern portion of the Murray Mallee division.

The farm has two distinct types of soil; the better of which covers about four-fifths of the total area, and is a red loam of good quality seated on a good retentive clay. Soil of this type usually carries good crops of Wheat when well managed, and should develop into good pasture under the influence of successive phosphatic dressings of crops. The balance of the land consists of sandhills, running East and West, and dividing up the loam into several sections. This light sandy land overlies a good clay subsoil at depths of 1ft. to 2ft. In dry seasons this light sandy land has usually carried better Wheat crops than the loam; but in dry years it is apt to drift over the heavier flats.

Clearing operations were started 22 years ago and were completed 5 years ago.

Improvements and Subdivisions are above average. The Homestead is centrally situated and well equipped with labor-saving devices. Farm buildings are adequate, special features being an excellent barn, implement shed and sheep yards. A central roadway runs North and South, with division fences running East and West to the boundaries. Boundary Fences are wire-netted and all division fences are Sheep-proof. Water has been reticulated from a central bore to practically all paddocks.

The farming plant is complete and efficient; and all machinery is kept in good order. Within recent years horses have been displaced by a tractor with a view to reducing labor costs. Live Stock generally are high class, and Sheep are the main revenue earners. The latter consist for the most part of good strain Merino Ewes, bred to Merino Rams, Suffolks or Corriedale, according to circumstances. A breeding flock of Corriedale Ewes is gradually being built up.

Farming practices on this farm are among the best in the district; all Wheat is sown on carefully prepared fallow. A three-course rotation is usually followed, namely—

1. Bare Fallow,
2. Wheat, and
3. Oats, the bulk of which is grazed.

Superphosphate has been used at the rate of 1cwt. to 1½cwts. per acre; and prior to the recent drought period the mean Wheat yield has usually been about 20bush. per acre.

Finally, the general location, the permanent improvements and the farming methods followed make of this Farm a good example of a modern Mallee Farm."

2. DISTRIBUTION OF FARM AREA AND CROP RETURNS IN 1929-30, 1930-31, AND 1931-32.

Mallee Farm No. 1 is 1,685 acres in area, distributed as follows:—

Buildings and Grounds	9 acres.
Roadways	7 "
Uncleared Scrub	14 "
Available Arable Land	1,655 "
<hr/>	
Total Farm Area	1,685 acres.
<hr/>	

The manner in which the available Arable Land was used for farming purposes during this period of three years is summarised below:—

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	Acres.	Acres.	Acres.	Acres.
Wheat on fallow	448	395	479	440·67
Wheat on grassland	—	23	—	7·67
Oats on fallow	27	—	33	20·00
Oats on grassland	120	61	—	60·33
Cereal hay on fallow	—	—	29	9·67
Grazing crops	539	492	—	343·67
Bare fallow	395	541	469	468·33
Area in cultivation	1,529	1,512	1,010	1,350·34

The Mean Yields per acre of harvested Crops were as follows:—

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	Bush.	Bush.	Bush.	Bush.
Wheat on fallow	14·35	15·60	19·35	16·20
Wheat on grassland	—	16·78	—	16·78
Oats on fallow	19·65	—	17·24	18·03
Oats on grassland	6·63	21·17	—	11·54
Cereal hay on fallow	—	—	Tons. 1·04	Tons. 1·04

Finally, if we take into consideration Areas grazed by Live Stock in the course of each season, and reduce Area in Cultivation to its twelve-month equivalence, the total available area can be shown to have been utilised as follows on next page.—

Distribution of Arable Area on Basis of 12 Months' Availability.

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	Acres.	Acres.	Acres.	Acres.
Harvested crops and fallow	732	757	758	749
Grazing crops	519	460	—	326
Total area in cultivation	1,251	1,217	758	1,075
Stubble grazing	140	120	135	132
Temporary natural pasture	264	318	762	448
Total available arable area	1,655	1,655	1,655	1,655

3. RAINFALL FOR 1929-32 IN COMPARISON WITH PRECEDING MEANS FOR THE DISTRICT.

In the matter of Crop yields, Rainfall dominates all other climatic factors in South Australia, and it follows that it is generally given special consideration in all discussions that concern Crops. In the data that follow, the distribution of the three years' rainfall has been contrasted with preceding means under special headings that concern normal crop development:—

	1929-30.	1930-31.	1931-32.	1929-32 Means.	Lameroo. 33 Years' Means.
	In.	In.	In.	In.	In.
Seeding rains (April-May)	1.91	2.26	2.36	2.18	2.89
Winter rains (June-July)	2.20	2.17	4.48	2.95	3.68
Spring rains (August-October) ...	2.64	7.36	3.26	4.42	5.47
Early summer rains (November) .	0.52	0.34	1.11	0.66	0.96
"Useful" rain (April-November)	7.27	12.13	11.21	10.21	13.00
Balance of season (Dec.-March) ..	4.09	1.97	3.70	3.25	3.10
Total 12-month fall	11.36	14.10	14.91	13.46	16.10

From the above it will be noted that both total and "useful" rainfall—April-November—were below normal in all three seasons; and it is in the main to this fact we must attribute a decline in crop yields relatively to those of earlier years. The 1929-30 season, in particular, must be considered as having been unfavorable.

PART II.—FINANCIAL.

1. CAPITAL ACCOUNT.

For the purpose of the analysis of these accounts, it has been assumed that the present owner had acquired the property on April 1st, 1929, on a walk-in walk-out basis, for £10,119 11s. 3d., and that the latter sum represented the original Capital upon which interest had been charged for distribution among the real accounts for the 1929-30 season. Actually, however, the property is a Crown Lease, subject to a covenant to purchase agreement extending over 65 years from 1921, and involving after the first five years 120 half-yearly payments of £86 10s. 9d. for Instalments of Principal and Interest.

A summarised statement of items included in the original Capital is given below; full details will be found in Table I. of the Appendix:—

	Values.		Percentage.
	Total.	Per Acre.	
	£ s. d.	£ s. d.	%
Land (1,685 acres)	3,832 0 0	2 5 6	37·87
Permanent improvements	2,843 0 0	1 13 9	28·09
Farming plant	1,355 10 0	0 16 1	13·40
Live stock (apart from horses)	827 0 0	0 9 10	8·17
Goods on hand	734 14 3	0 8 9	7·25
Field work and crops	527 7 0	0 6 2	5·22
Original capital, April 1st, 1929	£10,119 11 3	£6 0 1	100·00

It should be stated that, apart from the land, values shown in Table I. were determined by the owner and the District Agricultural Instructor (Mr. R. L. Griffiths) on the basis of early 1929 Values.

The value of the Land, on the other hand, has been determined by the Covenant to Purchase Agreement; and to this value has been added the estimated cost of clearing operations undertaken since the owner's occupancy of the property. It was recognised that the selling value of the land in 1929 was undoubtedly greater than £2 5s. 6d. per acre cleared; and that even at the present time its selling value is probably in excess of the latter figure. We did not, however, feel justified in accepting for the unimproved value of the land any more than the owner had actually paid or undertaken to pay; should the latter at a later date decide to sell the property he would then be in a position to benefit from any improvement in price that might obtain at the time; in such circumstances possible farming losses of the past would probably be made good.

During these three years Interest has been charged and debited against appropriate accounts at the following rates, namely, 5 per cent. against Land and Improvements and 6 per cent. against Floating Capital.

Attention is drawn to the fact that two-thirds of the value of the Capital invested is represented by Land and Improvements.

It has already been stated that the land is a Crown Lease held on a Covenant to Purchase Agreement; and it follows that the farmer does not own personally more than a proportion of the Capital value of the property; the outstanding Capital liability in 1929 was £3,257 5s. 9d. In addition, prior to 1929 the farmer had purchased Wire-netting from the District Council, re-payable in 16 yearly instalments; in the latter connection the sum outstanding in 1929 was £212 2s. 2d. Hence the farmer's personal interest in the property may be summarised as follows:—

	£ s. d.	£ s. d.
Land	574 14 3	
Improvements	2,630 17 10	
Farming plant	1,355 10 0	
Sheep	827 0 0	
Goods on hand	734 14 3	
Field operations and crops	527 7 0	
Owner's personal interest		6,650 3 4
Lands Department		3,257 5 9
District council		212 2 2
Original capital	£10,119 11 3	

The position of the Capital Account at the end of each of the three seasons with which we are concerned has been shown below in summarised form in comparison with the Original Capital; fuller details will be found in Table II. of the Appendix.

	Original Capital.	Capital, March 31, 1930.	Capital, March 31, 1931.	Capital, March 31, 1932.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Land (1,685 acres)	3,832 0 0	3,845 14 11	3,865 16 10	3,885 0 9
Improvements	2,843 0 0	2,818 8 9	2,719 6 9	2,753 15 1
Farming plant	1,355 10 0	1,666 8 0	1,376 5 0	1,128 0 0
Other live stock	827 0 0	345 17 6	258 13 0	297 10 0
Goods on hand	734 14 3	551 18 1	311 6 0	462 7 8
Field works and crops	527 7 0	324 1 11	328 17 11	324 7 2
Gross assets	10,119 11 3	9,552 9 2	8,860 5 6	8,851 0 8
Less Difference between sundry creditors and debtors	—	271 18 8	519 5 1	379 18 6
Net assets	£10,119 11 3	£9,280 10 6	£8,341 0 5	£8,471 2 2

The dwindling away of Net Assets in 1929-30 (£839 0s. 9d.) and in 1930-31 (£959 10s. 1d.) is clear indication of unsuccessful seasons; it was partly attributable to unfavorable weather conditions, but in the main to the calamitous fall in World prices for agricultural products. In 1931-32 World conditions were more favorable, the combined result of which led to an improvement in Net Assets from £8,341 0s. 5d. to £8,471 2s. 2d. These losses and gains will be examined in further detail under another heading.

2. INCLUSIVE YEARLY FARMING EXPENDITURE.

Inclusive Farming Expenditure incurred in any one year may be said to include items which can be separated out into two sections, namely:—

- Items of expenditure involving actual Cash Disbursements, or Loans; and
- Items of expenditure that are legitimate Bookkeeping Entries, but which do not involve actual Cash outgoings.

That items included in the first section form legitimate part of Costs of Production is, of course, obvious, but curiously enough there appear to be differences of opinion as to the validity of items included in the second section. This aspect of the position will be examined later on.

This Inclusive Farming Expenditure has been set out in detail for the three seasons under consideration in Table III. of the Appendix. The mean data for the three seasons may be summarised as follows:—

	Mean Annual Expenditure, 1929-32.		
	Total.	Per Acre.	Percentages.
I. Items involving cash disbursements—	£ s. d.	s. d.	%
1. Capital account	332 6 1	3 11	17.31
2. Wages	61 1 3	0 9	3.18
3. Services	49 4 8	0 7	2.56
4. Sundries	429 19 8	5 1	22.40
5. Interest on loans	203 4 0	2 5	10.58
6. Rates and taxes	29 18 5	0 4	1.66
Totals	1,105 14 1	18 1	57.59
II. Items not involving cash disbursements—			
1. Interest on owner's capital	314 12 1	3 9	16.39
2. Farm produce used on farm	190 10 6	2 3	9.92
3. Various	9 2 9	0 1	0.48
4. Value of owner's labor and management	300 0 0	3 7	15.62
Totals	814 5 4	9 8	42.41
Grand totals	£1,919 19 5	22 9	100.00

The above data show that over a period of three consecutive years the Inclusive Farming Expenditure of a 1,685 acre Mallee Farm has been at the mean rate of £1,919 19s. 5d. per annum, or 22s. 9d. per acre. Of this sum, £1,105 14s. 1d., or 13s. 1d. per acre, or, again, 57.59 per cent. of the total, represented actual Cash Outgoings, or corresponding Credit; and £814 5s. 4d., or 9s. 8d. per acre, or, again, 42.41 per cent. of the total, items of expenditure that did not involve direct cash payments.

It should be stated here that in the above data neither Depreciation on Permanent Improvements, nor on Live Stock and Plant have been taken into consideration. And yet the yearly wear and tear of working material, of which Permanent Improvements and Farming Plant form normal part in agricultural operations, tend progressively to reduce the value of the owner's assets, and as such can be considered as contributing legitimately to his yearly working Costs; and the same can be said of mortality and shrinkage in value of various forms of Revenue-earning Live Stock. Mean yearly Depreciation under the above three headings has been estimated for the three years under consideration at £570 10s. 3d.; the addition of the latter sum to other items of Expenditure would lead to the following results:—

	Total.	Per Acre.	Percentage.
	£ s. d.	s. d.	%
Items involving cash disbursements	1,105 14 1	13 1	44.40
Items not involving cash disbursements	1,384 15 7	16 5	55.60
Total expenditure	£2,490 9 8	29 6	100.00

3. FARM OUTPUT.

We shall now pass on to a consideration of the Farm Output realised during these three years and determine to what extent it proved adequate or inadequate to meet corresponding expenditure. Full details on the subject have been given in Table IV. of the Appendix.

In two out of the three seasons, namely, 1929-30 and 1930-31, Inclusive Expenditure was considerably greater than Net Farm Output, with resulting losses of £839 0s. 9d. and £939 10s. 1d. respectively. An examination of Table IV. will show that in very large measure these losses were attributable to the calamitous fall in the prices of rural products which was first felt in 1929-30. Thus, in the latter season Gross Flock Revenues of £533 19s. were reduced to Net Flock Revenue of £57 16s. 6d. only, because of a sudden fall of £476 2s. 6d. in the general value of the Flock. In the succeeding season (1930-31) losses were in the main attributable to the mean price of Wheat sinking to the lowest figure ever recorded in South Australia, and to continued decline in Flock values.

On the other hand, in the season 1931-32 Net Farm Output exceeded Inclusive Expenditure incurred by £130 1s. 9d.: this satisfactory improvement was attributable to improved weather conditions, an appreciable rise in the price of Wheat, and an upward tendency in Flock values.

The Mean Yearly Value of Farm Output during the three seasons may be summarised as follows:—

	Mean Gross Output Sold or Used.	Inventory Differences.	Mean Net Farm Output.		
			Total.	Per Acre.	Percent- age.
	£ s. d.	£ s. d.	£ s. d.	s. d.	%
Wheat	974 19 10	+ 6 11 11	981 11 9	11 8	71.62
Oats	83 17 1	+ 10 8 2	94 5 3	1 1	6.88
Cereal Hay	32 14 1	— 0 7 4	32 6 9	0 5	2.36
Straw	—	+ 1 1 5	1 1 5	—	0.08
Total farm crops ...	1,091 11 0	+ 17 14 2	1,109 5 2	13 2	80.94
Sheep	365 11 11	— 174 16 8	190 15 3	2 3	13.92
Miscellaneous	336 3 8	— 265 14 4	70 9 4	0 10	5.14
Grand totals	1,793 6 7	— 422 16 10	1,370 9 9	16 3	100.00
Add mean loss	—	—	549 9 8	6 6	
Mean Farming Expenditure			1,919 19 5	22 9	

We have here, therefore, an example of a Mallee Farm considerably above the average, which during these three years was worked at a mean Loss to the owner of £549 9s. 8d. per annum, or 6s. 6d. per acre. The price realised for Wheat on the farm during these years was as follows:—In 1929-30, 3s. 5d. per bushel; in 1930-31, 1s. 6d.; and in 1931-32, 2s. 5½d. (exclusive of 4½d. Federal Bounty). The position of the Farm during these three years is supported by a single Balance-sheet and Profit and Loss Account, shown as Tables V. and VI. in the Appendix.

4. MANAGEMENT AND LABOR INCOME.

The attempt will be made in the course of this Report to ascertain what have been during these three seasons the mean costs of rural undertakings under the conditions of this Mallee Farm; and as on the great majority of Mallee Farms, the owner is responsible not only for Management, but in addition for a major share in all manual operations, it has been necessary for our purposes to allot to the owner a fictitious sum for Management and Personal Labor. Towards this end a sum of £300 has been set aside and debited *pro rata* against accounts concerned; in this total is included £73 5s. 2d. (mean of 1929-32), representing actually the value of Interest and Depreciation on the Dwelling House, but which has been accepted as rent paid by the owner. In adopting this figure I do not think that we can be accused of extravagance for the provision that has been made for the management and much of the Labor of a 1,685 acre Farm.

But, from the data that have already been given it is possible to calculate the value of the Management and Labor Income of the owner, had no fictitious charge been made for his services as Manager and Farm Hand. Towards this end the Management and Labor Income can be taken to be the difference between the values of the Farm Output, on the one hand, and of Farm Expenditure (including Interest and Depreciation, but excluding any charge for the owner's services)

on the other. On this basis the Management and Labor Income in each year can be taken to have been represented by the Net Losses or Net Profits of each year, less or plus £300, that is to say:—

"True" Management and Labor Incomes.

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Season's Loss (—) or Profit (+)	—839 0 9	—939 10 1	+130 1 9	—549 9 8
Less Owner's Salary	300 0 0	300 0 0	300 0 0	300 0 0
Management and Labor Incomes ...	—539 0 9	—639 10 1	+430 1 9	—249 9 8

Hence, on what must be looked upon as the most reasonable basis of determination, the 1929-30 and 1930-31 Seasons resulted in negative Management and Labor Incomes for the owner, namely, —£539 0s. 9d. and —£639 10s. 1d. respectively. This means that not only did the owner receive no payment for his services during these two seasons, but he lost in addition the sum of £1,178 10s. 10d.

Fortunately, matters improved in 1931-32, during which season the Owner's Management and Labor Income rose to £430 1s. 9d., that is to say, £130 1s. 9d. more than the Salary allotted to him in these accounts. The Mean Management and Labor Income for the three years continued nevertheless to be represented by a negative quantity, namely—£249 9s. 8d., that is to say, no salary to the owner during three years and an actual loss at the rate of £249 9s. 8d. per annum.

In the circumstances, it might well be asked how the latter managed during those unsuccessful seasons, not only to meet the normal demands of life, but in addition to keep his farm going; and more generally, how the majority of farmers is able to cling to the land despite a succession of unfavorable seasons or of low prices. In the latter connection it should be recalled that in Farm Expenditure as summarised in Table III. of the Appendix, provision was made not only for interest due to the Owner's Creditors, but also for interest on his Personal Capital invested in the Farm. But when circumstances are such that the difference between Revenue and Expenditure is represented by a negative Management and Labor Income, it is legitimate to argue that however much in normal times a farmer might be entitled to interest on Capital invested in the farm, in exceptional ones such Interest must necessarily give way to the claims of personal Management and Labor for adequate remuneration. If this view be accepted—and it is difficult to see how it can be denied—revised Management and Labor Incomes would be as follows:—

Management and Labor Incomes when no provision was made for Interest on Personal Capital invested in the Farm.

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Interest on Owner's Capital	366 19 1	316 12 3	260 4 10	314 12 0
Normal management and Labor Income	—539 0 9	—639 10 1	+430 1 9	—249 9 8
	—172 1 8	—322 17 10	+690 6 7	+65 2 4

Thus, then, if no provision had been made for Interest on the owner's Capital, the Mean Management and Labor Income available during these three years would have been £65 2s. 4d. only; a sum which can hardly be accepted as adequate for the maintenance of a family and the working of a 1,685 acre farm.

Finally, it can be argued that the owner must be provided with the means of Livelihood before provision can be made for Depreciation on Improvements, Livestock, and Plant; in such circumstances available Management and Labor Incomes would have been as follows:—

	1929-30.	1930-31.	1931-32.	1929-32 Means.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Depreciation Charges	806 16 2	506 12 4	398 2 4	570 10 3
+ or—Management and Labor Incomes as above	—172 1 8	—322 17 10	+690 6 7	+65 2 4
	+634 14 6	+183 14 6	+1,088 8 11	+635 12 7

And thus eventually we are able to reach appreciable positive value for Management and Labor Incomes in each one of the Seasons under consideration, namely—

	£ s. d.
1929-30	634 14 6
1930-31	183 14 6
1931-32	1,088 8 11
1929-32—Means	635 12 7

All the above figures, with the exception of those of the 1930-31 Season, are in excess of the £300 stipulated as the owner's remuneration. We can say, however, of the mean of the three seasons that the owner could not have realised a Management and Labor Income of £300 per annum without foregoing all Interest on his Personal Capital and making provision for one-half only of normal Depreciation charges. It can be said, therefore, that during these unsuccessful years he has been living upon reserves built up in the past, or, in other words, upon his Capital. This view is supported by the general three-year Balance-sheet which is included in the Appendix as Table VI.

5. THREE-YEAR BALANCE-SHEET.

The general financial position of the Farm has been outlined in a single Balance-sheet, setting out the results of the transactions of three successive seasons.

Attention is drawn to the gradual reduction of the owner's Capital under the influence of unfavorable seasons and low prices. On the 1st April, 1929, this Capital had a value of £6,650 3s. 4d.; by the 31st March, 1930, it had been reduced to £5,811 2s. 7d., a decline of 12.62 per cent.; and by the 31st March, 1931, to £4,871 12s. 6d., representing a total decline of 26.74 per cent. relatively to the Original Capital. Fortunately, matters improved somewhat in 1931-32, and the value of the owner's Capital rose to £5,001 14s. 3d., an improvement of 2.67 per cent. on the 1930-31 value, but still 24.79 per cent. below the value of the original Capital.

The owner of this property can be accepted as a good example of a successful farmer, who until three years ago was able to consolidate his position and build up reserves, upon which he has been compelled latterly to draw. He has met bad seasons and low prices by reducing his expenditure, and in spite of losses is in a good position to take full advantage of the inevitable turn in the tide. Unfortunately, his case, without being unique, is very far from that of hundreds of farmers who have been unable to meet adverse conditions as successfully, and who, unless assisted in some manner or other, are in danger of losing their farms.

6. PROFIT AND LOSS ACCOUNT.

A single Profit and Loss Account has been prepared for the three seasons and placed in the Appendix as Table V.

It will be seen that, taken in the aggregate, all Real Accounts closed on a debit at the end of the three years, namely:—

	£	s.	d.
Sheep Account	902	2	7
Wheat Crop Account	405	5	7
Oat Crop Account	265	16	1
Hay Crop Account	54	4	0
Stores Account	21	0	10

Aggregate Three Years' Loss .. 1,648 9 1

Of the three main accounts, Sheep and Oats showed losses in each of the three years; Wheat showed losses of £171 7s. 3d. and £473 2s. 1d. respectively in 1929-30 and 1930-31; but a profit of £239 3s. 9d. in 1931-32.

It will be observed that in the aggregate the three Seasons closed on a Loss of £1,648 9s. 1d., but it should be added that during that period Interest on Owner's Capital was credited with £943 16s. 2d., and General Depreciation with £1,711 10s. 10d., making an aggregate of £2,655 7s.

FROST PREVENTION BY ORCHARD HEATING.

[By J. B. HARRIS, Dip. Hort., Horticultural Instructor.]

The necessity for any possible action which is economically practicable to prevent frost damage in orchards and vineyards has been drawn attention to in the Barossa and Clare districts by the devastating late spring frosts which have destroyed fruit and vine crops in parts of these districts during four of the past six years. The districts mentioned are probably no more, indeed they are possibly less, subject to late spring frosts than many other parts of South Australia, but being otherwise almost ideally suited for the growth of all temperate climate fruits, such as apricots, &c., and vines, these fruits have been extensively planted and their cultivation is now of great economic importance to the State. Although frosts of a few degrees intensity are of comparatively frequent occurrence during the winter months they do not occur with great frequency during the latter part of September, throughout October, and during early November, and indeed for many years prior to 1927 no crops were lost through the agency of spring frosts; a very severe late frost was experienced at Angaston about 1914, and old established growers still speak of a bad spring frost in 1900. It is probable that years of late spring frosts may recur in cycles and that in intervening years orchard and vineyard heating in these districts will not be necessary.

On account of the losses experienced by growers the question of frost prevention was placed on the agenda of the Non-irrigated Fruit Areas Bureau Conference held at Clare in November, 1931, and was there freely discussed, the consensus of opinion appearing to be that smudging, or, in other words, endeavoring to envelop the orchard or vineyard in smoke, was the only remedy, and most growers who had attempted this had not achieved great success.

The Chief Horticultural Instructor, Mr. Geo. Quinn, published a report (see *Journal of Agriculture*, June, 1932) dealing with the subject of smudging and orchard heating as carried out in other countries. The question of smudging was then taken up by a large number of fruit and vine growers in the Light's Pass area, who formed a body known as the Light's Pass Frost Fighting Committee. These growers to the number of about 30 made preparations for smudging on an extensive community basis; they also arranged for all members to be advised by urgent telephone message in the case of a damaging frost. When the first serious spring frost occurred in 1932 the smudging scheme was carried into effect, and though an extensive smoke was caused by this community effort it slowly but surely drifted to a slightly lower elevation, following the direction of the river to the other side of Nuriootpa township, and the crop on the low-lying parts of Light's Pass was almost entirely destroyed by frost. It may be of interest here to record that fruit and vine crops did not suffer that night in the locality where the smoke drifted, although growers in that area made no attempt to generate smoke. The following night they did not generate any smoke, nor did they receive any from Light's Pass and their crops were then destroyed by frost. This latter statement by no means proves that smoke saved the crops on the first night, observations having proved that these late spring frosts are exceedingly patchy in their occurrence.

Smudging should not, in the writer's opinion, be entirely condemned as useless, as, from observation in the northern districts, and from the literature of other countries, and discussion with persons who have had first hand experience of smudging as applied to continental vineyards, it would appear that where the topography of the country is suitable and the smudging can be held as a dense

pall of smoke in the low-lying areas, and also provided the smoke pall is created sufficiently early, the radiation of the earth's heat can be checked to such an extent as to prevent freezing, while the temperature on the unprotected areas has fallen to one, or in some cases, two degrees below freezing point. It is also worthy of note that the system of heating with which this article mainly deals resulted, in addition to the generation of heat, in a dense pall of very black smoke throughout the orchard, and appearing from a distance to be suspended among and above the tops of the trees at a height of about 8ft. from the ground.

A point which aroused considerable interest in January, 1933, was the chance observation that trees in the immediate vicinity of seven smudge fires lit in the middle of Mr. P. B. Boehm's orchard were carrying a good crop of fruit on the side of the trees nearest to the fires in the case of six of the fires and a much lesser crop around the seventh fire which had been allowed to go out on account of the difficulty of adequately tending a number of fires. The remainder of the trees, which received only the drifting smoke, bore no fruit, and those trees in the immediate vicinity of the fires bore fruit on the sides near the fire only; this latter point was most conspicuous and a count of the fruits on one tree showed on the side near the fire 615 fruits and on the side farthest from the fire 96 fruits. This observation stimulated the interest of those who saw it in further investigation of orchard heating under local conditions.

Throughout this time the matter was being discussed by members of the Light's Pass Agricultural Bureau with a view to having a test of orchard heating carried out by the Department of Agriculture. Messrs. S. and L. Plush, of Light's Pass, took a prominent part in the movement and Mr. S. Plush reported having saved a crop of apricots from frost on a small area at Light's Pass in 1900 by burning coal, wood, and kerosene in improvised heaters.

The matter was again discussed at the Non-irrigated Fruit Areas Bureau Conference, this time at Tanunda in November, 1932. The report by the Chief Horticultural Instructor was read and the writer of this article also spoke on the question of heating in its specific relation to occasional late spring frosts as they occur in this district. As an outcome of the discussion Mr. K. Robinson, Hon. Secretary of the Angaston Agricultural Bureau, was requested to organise a special meeting of Bureau members to consider the question. This meeting was convened at Nuriootpa on December 15th, 1932, the following Branches being represented:—Angaston, Light's Pass, Lone Pine, Lyndoch, Greenock, Springton, and Penwortham. This meeting formed the South Australian Frost Combating Committee, comprising two delegates from each of the Branches alluded to, with an executive committee consisting of Messrs. P. B. and F. W. Boehm, L. Plush, K. Robinson (secretary), and the writer. The executive committee later decided on a levy on all Branches represented, the sum raised being necessary for preliminary tests, and also requested that the writer's services as a departmental officer be placed freely at the disposal of the committee. This request was granted and consequently since then a considerable time has been devoted to investigation of frost prevention. The writer suggested to the committee that an experiment such as that carried out by the New Zealand Department of Agriculture in 1927 and along the lines of the simplest form of orchard heating as carried out in California should be undertaken here. A statement of estimated costs was submitted, and the scheme was approved by the executive.

Before recommending to the committee the scheme above referred to many inquiries were made, but little information was obtained, relative to tests of orchard or vineyard heating as distinct from smoking or "smudging" which had been carried out in South Australia or adjacent States. The only definite record of a test was received through the State Electricity Commission of Victoria who kindly supplied detailed information and temperature graphs, showing results

of heatings carried out by Mr. J. A. Egan, of Gonn Crossing, Victoria, who used kerosene tin heaters, and briquettes supplied by the State Electricity Commission in 1929, and thereby succeeded in profitably saving a crop of $3\frac{1}{2}$ acres of mandarins. The heaters used were constructed from one and a half kerosene tins, the tins costing at that time 3d. each, but these heaters ultimately proved unsatisfactory as the tins burned out after two or three firings. The present cost of kerosene or petrol tins in Adelaide is rather more than 1s. each. No record was obtained of tests conducted in Australia with oil fuel heaters of the type used in California and New Zealand.

At about this time Mr. W. Gilbert, of Wongalere, near Williamstown, made exhaustive inquiries from various sources on frost prevention in its application to vineyards, and eventually imported sample heaters from New Zealand, which, together with all information he had collected, he kindly made available to the South Australian Frost Combating Committee. Members of the committee also conferred with Mr. Kelly, of Lyndale Vineyards, near Lyndoch, on the subject of frost prevention, and inspected various frost alarm devices which were in use there.

The test recommended was to heat 1 acre of apricot trees with heaters of the "lard pail" type and use for purposes of comparison 1 acre of apricot trees unheated and growing under otherwise exactly similar conditions alongside. The 2 acres of trees selected as being most suitable for the test were finally found in the orchard of Mr. P. B. Boehm, at Light's Pass, who has whenever necessary given all possible assistance in carrying out the test.

Before proceeding to a discussion of the test it may be well to consider briefly the various frost conditions which occur and such as are known as "white frost," "black frost," and a "freeze." The condition, which is common to all these frosts, whatever may be the term by which they are locally described, is a lowering of the atmospheric temperature, within a few feet of ground level, or at that and greater altitudes, to 32° F. or lower. This condition is essential to a frost of any kind, and anything which will prevent such a condition will prevent a frost of any sort. This latter may seem to many persons an obvious statement of fact, but within the writer's experience there are many growers who contend that nothing can be done against a black frost, whereas the test herein described showed evidence that heating (such as from 2.45 a.m. to 6.30 a.m. on October 26th) is effective against a black frost as it is against a white or hoar frost. A white frost, so named from the particles or frozen moisture or dew, which are seen deposited on all objects in the frosted area differs only from a black frost inasmuch as in the case of black frost there is too little moisture in the atmosphere for the moisture to be frozen and deposited as in the case of a white frost. A black frost usually follows a white frost where two frosts occur on consecutive nights, the dew having been frozen on the first night, and the temperature not having risen sufficiently on the following day to vaporise the moisture and thus recharge the atmosphere with moisture to be deposited as white frost. Thus a black frost, by reason of the fact that it frequently follows a white frost, is often assumed to be more destructive in its effect, whereas what is really seen after a black frost is frequently the cumulative effect of two frosts. Such a condition as that just described occurred at Light's Pass during the early morning hours of October 25th and 26th. The frost on the 25th being a white frost and that on the 26th a black frost, although the minimum temperature reached on the 25th, i.e., 28.5° F. was one degree lower than the minimum reached on the 26th, i.e., 29.5° F.

In the case of local frosts, such as those just referred to, the lowering of temperature is caused by radiation of the earth's heat and consequent inversion of the strata of atmosphere near the earth's surface. This class of frost usually

occurs in the early hours of the morning, say, between 2 a.m. and 6 a.m. It is the usual cause of damage in this district and consequently the more expensive form of heating, as used in the case of a "freeze" lasting throughout the night, is not necessary.

A "freeze" is the term used on the Pacific Coast to describe the type of frost which follows a cold windy day with a cloudy sky, the day conditions being such that the earth and adjacent atmosphere receives little heat from the sun and consequently the earth has little heat to radiate and thus warm the atmosphere during the night. The result of this is that the little surplus heat of the earth is exhausted by radiation to the atmosphere late in the afternoon or early evening, the air adjacent to the earth then becomes cold by atmospheric inversion, and lack of radiation from the earth, and a frost results early in the night, which will probably last till sunrise or till the advent of a warm wind. The severe frost which destroyed the crops in the Murray Valley in 1927 was in the nature of a freeze.

It will also be well to consider what is meant by "radiation" and by "atmospheric inversion" or "air drainage."

All persons who have warmed themselves at a fire have in so doing absorbed heat rays which are radiated by the fire during the process of burning; the body which has absorbed the heat rays cannot, however, retain them indefinitely and thus in turn it radiates heat to the surrounding atmosphere. Similarly, the earth exposing itself to the sun's rays during the day time absorbs heat rays from the sun and becomes warm, the degree of warmth varying according to the kind of earth, and its moisture content, and the amount of sunshine. All substances thus exercise the power of absorbing heat from any warmer substance with which they come in contact, and *vice versa* they transmit heat to cooler articles with which they come into contact. In considering this matter in its relation to orchard and vineyard heating we find that the earth, and more particularly the surface earth, is absorbing heat from the sun from sunrise till sundown. Similarly, the atmosphere is absorbing heat from the sun, although the temperature of the atmosphere is not so great near the earth's surface as is the temperature of the earth itself because the atmosphere does not absorb heat so readily. Thus by about 3 p.m. on an October afternoon the earth's surface temperature is greater than that of the air with which it is in contact and consequently the earth proceeds to give out or "radiate" heat to the surrounding atmosphere until such time as the temperature of both is equalised.

Atmospheric inversion or "air drainage" results from the expansion of matter which takes place when the matter is heated, the result being that the density, or weight per given volume, decreases, *i.e.*, the substance becomes lighter per unit of bulk when heated. Thus, when the air in contact with the earth's surface is heated it expands and becomes lighter than other air not so directly heated and which lies above it; the natural result of this is that the heavier cold air falls to the the earth's surface, changing place with the warmer air, and thus we have atmospheric inversion, resulting in the air, say, 30ft. above the earth's surface being measurably warmer than air at the earth's surface. This tendency of the earth to radiate its heat in the late afternoon, evening, and during the night at a greater rate than it is receiving heat from the sun (in order to heat the air near its surface), and the tendency of the air thus heated to be displaced by the colder air immediately above it (so bringing cold air into conjunction with cold earth) is the cause of the frosts which we have to combat. Although all frosts are more or less due to radiation, the severe "freezes" have as a large contributing factor insufficient absorption of sun heat as a result of cloud and cold winds during the daytime. Evidence of air inversion or atmospheric drainage

or the tendency of cold heavy air to drift to lower levels is frequently seen in vineyards planted on sloping land or on a hillside which merges into level lower ground, where the vines on the low level are cut by frost and those above a certain clearly defined level on the higher ground escape. Many growers are also familiar with the phenomenon that vines on very recently cultivated land are more liable to frost injury than others on land not so cultivated; this would appear to be due to the recent cultivation affecting the rate of heat radiation.

Summarising the points of absorption and radiation of heat and temperature inversion we conclude that—

The earth and the atmosphere receive heat from the sun's rays during the day time.

The earth absorbs more heat and gets hotter than the air.

The earth gives heat to the air which is in contact with it.

The earth thus during the night time gives out more heat than it receives and thereby becomes cold.

The air which is heated by the earth is displaced upwards by the falling of the heavier, cooler air above it.

Thus cold air comes into contact with cold earth and where the action continues long enough a frost results.

Blanket of naturally warmed air here resulting from temperature inversion. This makes orchard heating possible.

Fig. 1.—To illustrate the path of heated and gradually cooling air currents. (Adapted from U.S.D.A. Bulletin, 1588.)

It should be noted that the air warmed near the earth's surface will only rise through colder air; and will not rise, but will tend to mix when it meets with air of equal temperature until it becomes cool or displaces cooler air; this results in a mixing of the strata of air near the earth's surface, which is most easily illustrated when the heat is generated at given points as in orchard heating (see Fig. 1.)

Having visualised the possibilities of orchard heating, the executive committee ordered sample heaters from two Adelaide firms. The specifications for these heaters were taken from the *New Zealand Journal of Agriculture* for August, 1928, and were as follows:—Diameter at bottom 7½ in., at top 9½ in.; height, 8½ in.; bodies, 26 gauge black steel, top wired, bottom double seamed; spreaders, 18 gauge black metal with welded arms; lids, 26 gauge black steel with ¾ in. flanged rim. The necessary lighting torch was copied from a photograph and description in the University of California Bulletin No. 398, the reference to "Torches and Torch Fuels" being as follows:—"A torch consists of a container with a spout, a wick, and a wire gauze in the base of the spout. The wick is made of asbestos, usually wrapped in a piece of screen. It is placed either directly in the spout, loosely enough so that the fuel will flow freely through it, or in a slot close to

the end of the spout. In either case the wick must be so arranged that the fuel leaving the spout flows over or through it. The lighted wick ignites the torch fuel as it flows out. The most important feature of the torch is the protective wire gauze at the base of the spout, and under no circumstances should a grower use a torch in which the wire gauze is lacking or defective. The gauze is of fine mesh brass or copper screen and is generally soldered into the base of the spout. It works on the same principle as the miner's safety lamp, the flame of the burning gas being cooled below the kindling point by the screen and not passing through to the reservoir below. Slight explosions sometimes occur in the spout, but the gauze prevents a disastrous explosion of the container. The spout should screw tightly on to the container against a metal gasket. The torches are usually filled with a mixture of equal parts of gasoline and kerosene. This mixture will carry fire clear to the ground if poured from a burning torch and give a fire hot enough to light heaters readily. An extra supply of torch fuel should be kept in some airtight container such as a 5gall. can or 15gall. oil drum in the field. It is a wise precaution to fill torches only by electric light."

The following are dimensions of the torch which was used in this test:—Container—Diameter, 6in.; height, 9in.; height to top of dome, 10½in. Spout—Diameter at union end, ¾in.; at wick end, ¾in.; length of spout, including union, 13in., and which contains approximately 1gall. of fuel. (See Fig. 2, showing torch, burning pail, spreader, and lid.)

Fig. 2.—Liquid fire torch and burning pail with flame spreader and lid.

The Shell Oil Company kindly donated two samples of oil which they considered would be suitable, namely, "fuel" oil and "solar" oil.

Of the sample heaters supplied, some were of black iron and one was galvanized after manufacture.

An endeavor was made to carry out a preliminary burning test on July 24th with three black iron heaters and one galvanized. The black iron heaters were found to leak slightly at the seams; the galvanized pail did not leak. The heaters were immediately emptied as the oil was likely to be injurious to plant roots if it seeped into the soil in any quantity. The black iron pails were then soldered along the seams as a temporary measure. In lard pail heaters, which later arrived from New Zealand, it was seen that all seams are brushed on the inside of the bucket with what appears to be bituminous paint to prevent leakage.

On July 26th—Burning rates of Shell "solar" oil and Shell "fuel" oil were tested in four heaters. Shell fuel oil in heater with spreader on all the time burned 4 hours 6 minutes. Shell solar oil in heater with spreader on all the time

burned 4 hours 35 minutes. Shell fuel oil with spreader removed after 3 hours' burning burned 3 hours and a half. Shell solar oil with spreader removed after 3 hours' burning burned 3 hours 37 minutes. One gallon of oil was used for each of the four tests and as fuel oil costs approximately 6d. per gallon and solar oil 9d. per gallon, it was then decided to use fuel oil in all future tests. This test was carried out between 7.30 p.m. and midnight.

Following the success of this first burning test it was found that satisfactory heaters (galvanized), complete with spreader and lid, could be manufactured in Adelaide and sold in lots of 150 at 2s. 10d. each. All expense up to this time had been borne by the South Australian Frost Combating Committee—incidentally the first sample heaters cost considerably more than 2s. 10d. each—and the committee now decided to bring the matter under the notice of the Minister of Agriculture and request that a sum of money should be made available to the Department

Fig. 3.—U tube thermometer, showing connections to electric bell alarm.

of Agriculture sufficient for the purchase of all equipment for an experimental heating of 1 acre of orchard. This request was granted and the following equipment purchased:—

- 120 lard pail type 5-quart orchard heaters.
- 1 torch lighter.
- 5 minimum alcohol thermometers.
- 1 frost alarm thermometer with wiring battery and bell.
- 360galls. of Shell fuel oil.

On August 12th—All thermometers for use on the experimental plots were tested at the Adelaide Observatory and found to be, with one small variation, correct for the purposes of this experiment. I would here acknowledge our indebtedness to Mr. Bromley, the Government Meteorologist, for his valued help and advice in the conduct of these experiments.

August 28th—The frost alarm thermometer was installed at the home of Mr. F. W. Boehm and tested by spraying with ethyl chloride to lower artificially the temperature. For this test we are indebted to Dr. A. Scholz of "The Willows"

Hospital. The thermometer and electric bell alarm functioned accurately when thus tested. The thermometer (Fig. 3) was placed about 9in. above ground level facing east on land approximately of the same level as the orchard where the tests were carried out. Mr. F. W. Boehm's house was the nearest home to the orchard.

August 29th—Levels were taken for comparison of altitude at various points on the "heated" and "check" plots. The greatest variation of level over the heated area was found to be 14in. The check plot was found to be generally 10in. higher than the heated plot, so that any advantage in the matter of altitude affecting temperature would be with the unheated area.

August 29th—Five minimum alcohol thermometers were installed in thermometer shelters erected on posts, the shelters being made from fruit cases with the bottom and one side knocked out and the outside of the case painted white, the open side of the shelter facing south. Four of the thermometers were erected on the heated plot to enable tests to be made of the comparative heat generated at different points; these were marked and subsequently referred to as B, C, D, E. One thermometer marked A was installed in the same manner on the check plot to record the temperature on the unheated area. The height of the thermometer is 3ft. above ground level. The thermometers were placed with a fall of 1in. towards bulb end (*see Californian Bulletin 398, p. 38*), but it was later found necessary to correct this as the thermometers used in this experiment are so constructed that when placed horizontally the bulb is approximately $\frac{1}{2}$ in. lower than the stem. The altered position of the thermometer is shown in Fig. 4; in this position they worked satisfactorily. The minimum temperature is recorded by these thermometers by means of a small indicator which is drawn down the column by the surface tension of the alcohol; as the temperature rises, and consequently the spirit indicator—the small indicator—remains stationary at the lowest point to which it has been drawn. To record the minimum temperature each 24 hours it is, of course, necessary for those indicators to be set each day, and this is only one of the many operations carried out by Mr. P. B. Boehm during the course of this experiment.

August 29th—One hundred and twenty-seven heaters were charged with approximately 1gal. of oil each and covered with spreaders and lids.

September 1st—Portion of the area which is a low-lying frost pocket, became flooded by the overflow of the North Para River during the night of August 31st. Lids were lifted off heaters and blown away by the gale and rain fell into them and caused the oil to overflow; also, some heaters were washed away and others inundated by the flood, so that all the oil from those heaters floated away. This misfortune involved the loss of about 40galls. of oil, but could not be foreseen in time to prevent it; it would not be mentioned here but for its important bearing on the subsequent burning rate of the oil. All the heaters were finally recovered from the flooded area, the oil was separated from the water as far as possible, the heaters were refilled where necessary, and the spreaders and lids replaced with a brick or other heavy object on each lid to prevent it being again blown off. The refilling of the heaters was done on September 13th, and the heaters were lighted for the first time that night to ascertain whether the adulterated oil would burn and also to ascertain the amount of time required to light 127 heaters with one lighting torch. The result of this test was that the fuel appeared to burn satisfactorily, but the 127 heaters took 50 minutes to light. This was, of course, the first time most of the heaters were lit, and it has been reported elsewhere, and confirmed here, that they can be much more readily lighted after having been once burned. It was, however, decided to alter slightly the construction of the lighting torch to help in the more rapid lighting of the heaters. In the original construction of the torch

the wick, in the form of a piece of loosely twisted asbestos rope, was inserted into the spout of the torch with a piece of wire gauze fastened across the end of the spout to prevent the wick from falling out; with the wick in this position the liquid fire dripped from the spout of the torch when lighting heaters. To hasten the rate of lighting heaters, the wick was removed out of the spout and enclosed in wire gauze, which was wired to the under side of the spout with the wick protruding just beyond the spout; in this position the liquid fire poured over the burning wick into the heaters and thus reduced the person's time taken to light the heaters to half.

The temperatures recorded immediately after lighting heaters on September 13th were—A (check plot), 42 degrees; B, C, D, E (heated plot), 47, 47, 47, and 46.5 degrees respectively at 9 p.m. It is evident from these figures that the temperature of the heated plot had increased considerably during the 50 minutes occupied in the lighting of the heaters. Temperatures recorded 10 minutes later were—A, 42 degrees; B, 48.5 degrees; C, 48.5 degrees, D, 49.5 degrees, and E, 48 degrees, showing that the average temperature had advanced 1.75 degrees in 10 minutes on the heated area. At this time there were more clouds in the

Fig. 4.—Minimum Alcohol Thermometer set Horizontally in Shelter, and Heaters in Position in Orchard.

sky and a distinct drift from the north-east. As there was no frost on this occasion all the heaters were then extinguished by placing the lids on the heaters at 9.10 p.m. At 10.10 p.m.—one hour after heaters were extinguished—the temperatures recorded were—A, 40 degrees; B, 41 degrees; C, 42 degrees, D, 42 degrees; and E, 42 degrees.

September 14th—Readings of thermometers showed that no frost had been recorded to date.

September 21st—The frost alarm bell rang at 3 a.m. and the alarm was telephoned to me at Gawler. I reached the plot at Light's Pass at 4.3 a.m. Mr. F. W. Boehm had, in accordance with my instructions, lighted 127 heaters. These heaters were lit with spreaders on, which militated against a rapid increase in temperature. Temperatures recorded prior to 4 a.m. and immediately prior to lighting of heaters were—A (check plot), 37 degrees; B, 36 degrees; C, 34 degrees; D, 32 degrees; and E, 36 degrees. Temperatures recorded at

4 a.m. were—A, 39 degrees; B, 40 degrees; C, 39 degrees; D, 41 degrees; E, 40 degrees. It will be seen from these records that the temperature on the unheated check plot had risen 2 degrees, and this being so, all heaters were extinguished at 4.15 a.m.

September 24th—Frost alarm bell recording 34 degrees F. rang at 3.30 a.m. Mr. B. Boehm read all thermometers at 3.30 a.m. and subsequently until 5.15 a.m., and recorded the following temperatures:—3.30 a.m.—A, 34 degrees; B, 34 degrees; C, 34 degrees; D, 34 degrees; E, 34 degrees. 3.45 a.m.—A, 33.5 degrees; B, 33.5 degrees; C, 34 degrees; D, 33 degrees; E, 34 degrees. 4 a.m.—All 33 degrees. 4.28 a.m.—A, 33 degrees; B, 32.5 degrees; C, 33 degrees; D, 32.5 degrees; E, 32.5 degrees. At this time the alarm was telephoned to me at Gawler. I advised Mr. B. Boehm to light heaters at his discretion, and I left Gawler for Light's Pass. 4.35 a.m.—Mr. Boehm commenced lighting every other heater, and lit 58 heaters without removing spreaders. 5 a.m.—A, 32.5 degrees; B, 34.5 degrees; C, 34 degrees; D, 34.5 degrees; E, 34.5 degrees. 5.15 a.m.—A, 33 degrees; B, 35.5 degrees; C, 34 degrees; D, 35.5 degrees; E, 35 degrees. 5.40 a.m.—By this time I had arrived at the plot and recorded the following temperatures:—A, 32.5 degrees; B, 35 degrees; C, 33.5 degrees; D, 36 degrees; E, 35.5 degrees. As thermometer "A" on check plot was above freezing point and sunrise was approaching, all heaters were extinguished by 5.52 a.m. 6.03 a.m.—A, 32 degrees; B, 33.5 degrees; C, 32.5 degrees; D, 33.5 degrees; E, 33.5 degrees. 6.33 a.m.—A, 32 degrees; B, 32 degrees; C, 32 degrees; D, 32 degrees; E, 32.5 degrees. 7 a.m.—A, 34 degrees; B, 34 degrees; C, 34.5 degrees; D, 34 degrees; E, 34.5 degrees. On this occasion 12 heaters to the north and east of thermometer C were not lit, as at the time of lighting thermometer C showed a slightly higher reading than other thermometers on the heated plot.

October 1st—Hoar frost deposit was observed at Angaston, and slight hoar frost at Mr. P. B. Boehm's homestead, which is situated about 1 mile north of the experiment plot and the alarm thermometer. This frost was noticed at 6 a.m. Clear sky, still atmosphere, and falling temperature at Gawler between 9 p.m. and 10 p.m. on September 30th indicated likelihood of frost. Alarm did not ring. Readings of minimum thermometers on check and heated plots taken at 7 a.m. on October 1st, 1933, showed that minimum temperatures recorded during the past night were—A, 35 degrees; B, 34.5 degrees; C, 35 degrees; D, 34.5 degrees; E, 34.5 degrees; all corroborating the inference that the alarm thermometer did not fall to 34 degrees, at which temperature it is set to ring.

October 24th—Called to Light's Pass at 2.10 a.m. on account of alarm bell having rung at 34 degrees. The following observations of temperature and atmospheric conditions were made:—2.30 a.m.—Sky clear, no clouds, stars bright. Temperatures—A, 35 degrees; B, 34 degrees; C, 34 degrees; D, 34 degrees; E, 34 degrees. 3 a.m.—A, 34 degrees; B, 33.5 degrees; C, 34 degrees; D, 34 degrees; E, 33.5 degrees. 3.30 a.m.—Clouds appearing; A, 35 degrees; B, 34 degrees; C, 35 degrees; D, 34 degrees; E, 34 degrees. 4.30 a.m.—Dawn, sky overcast; A, 37 degrees; B, 37 degrees; C, 37 degrees; D, 37.5 degrees; E, 37.5 degrees. 5 a.m.—A, 39 degrees; all the rest 40 degrees. The night was calm throughout.

October 24th and 25th—Owing to an unfortunate breakdown of the alarm system no alarm was given when the temperature fell to 34 degrees on the night of October 24th, or early morning of October 25th, and many crops in the district were damaged by a frost which was recorded on the plot thermometers as 28.5 degrees.

The frost recorded, *i.e.*, 28.5 degrees F., destroyed a large proportion of the fruit on the plot which should have been heated and on the check plot, as well as in other orchards throughout the district; the characteristic small white spots which are seen on frosted apricots indicated a few hours after sunrise that much

fruit had been destroyed, but as the crop was an exceptionally heavy one, it appeared likely that a small proportion of the crop might have escaped, and it was therefore decided to continue the test in the event of another frost occurring—as it did on the following night—as in any case a further test would result in added data of results of heating under frost conditions. At the time of writing (November 23rd, 1933) it appears that a proportion of the crop did escape the first night, and was saved by heating on the second night (October 25th and 26th) on the heated plot, although the second night of frost almost completely destroyed the crop on the unheated plot. The results of the heating expressed in terms of fruit harvested from the heated and unheated plots will be published at a later date.

This breakdown of the alarm system was investigated by members of the Executive Committee, together with the writer, about two hours after Mr. F. W. Boehm had reported that a severe frost had occurred and the alarm bell had failed to ring. The U tube alarm thermometer which is connected to an electric bell system is so arranged that the electric current passes through the mercury column and so completes the circuit and rings the bell when the temperature reaches 34 degrees. Mr. Boehm reported that the bell had not rung, and when he examined the thermometer at daylight the mercury was still well beyond the point of contact although the bell was not ringing. The bell had always rung previously when the mercury reached 34 degrees and thus made contact, and when tested by spraying, as already mentioned, with ethyl chloride, in the presence of members of the Committee it was found that the bell rang perfectly when 34 degrees was recorded.

As in the case of frost prevention by orchard or vineyard heating the alarm system is of paramount importance, it is considered worth while to give here a likely explanation of the failure of the alarm. Also it is deemed worth while to quote "Californian Agricultural Extension Service," Circular 40, which unfortunately, was not to hand when this test was set up. With reference to thermometers this circular states, pages 37 and 38, "The U tube type of thermometer which reads both maximum and minimum is very likely to be out of order, and is not recommended for use in connection with orchard heating." And again, "In districts where there are no frost warning patrols frost alarms are frequently used. In order to be safe they should be of the type that rings when the circuit is *broken* rather than when the contact is made. If anything goes wrong with the line the bell rings. This will occasionally result in the grower being called too soon. The alarm should be tested each night by pulling the switch."

Fig. 5 represents an ordinary maximum and minimum U tube thermometer with electrical contact points for use as a frost alarm, the sketch being made from the thermometer used in the experiment referred to. When the temperature is falling the mercury column D falls in the right hand tube and rises relatively in the left hand tube. When the temperature falls to 34 degrees F. the mercury rises sufficiently high in the left hand tube to connect the electric wires which are inserted into the tube from the terminals A and B, thus the electric circuit is completed and the alarm bell is rung. Should a bubble or a break appear in the mercury column between the wires inserted from terminals A and B as at C, the electric circuit will not be completed although the mercury has fallen below 34 degrees on the right hand column and risen above 34 degrees on the left hand column. Such a break is known to have occurred in this particular thermometer on a previous occasion, and it is presumed that the column again broke when the apparatus failed to ring the alarm bell when the temperature reached 34 degrees F. on the night of October 25th or early morning of October 26th. Although this alarm system has operated quite satisfactorily on very many occasions when chilled artificially or naturally during a period of 59 days it is known to have

developed a break in the mercury column once during that period, and it is now assumed that it developed a similar fault on the occasion when it failed to work the alarm bell.

Fig. 6 represents an ordinary thermometer fitted with terminals and wire inserts and wiring for frost alarm purposes. This type of frost alarm thermometer is designed to ring the alarm bell when the continuous electric circuit which is passing from terminal A to B through the mercury column D is broken by the mercury

Fig. 5.—Maximum and minimum U tube thermometer.

Fig. 6.—Ordinary thermometer fitted with electric terminals.

column falling below 34 degrees, at which point the wiring from terminal A is inserted. Similarly, if a bubble or break should accidentally form in the mercury column between the points A and B the alarm bell will ring on account of the

Fig. 7.—Graph illustrating record of heating on October 26th.

broken circuit. With the latter type of alarm two circuits—one of which is continuous, and operating a switch by means of a magnet—are used, the second circuit operates the bell. When the first circuit is broken through the temperature falling below the point A the magnet releases the switch which brings the second circuit into operation and thus the alarm bell is rung.

Unfortunately neither of these types of thermometers were obtainable when the breakdown in the thermometer which was in use took place.

On October 26th the alarm bell rang at 12.30 a.m., indicating that the temperature had fallen to 34 degrees F. on the alarm thermometer, which, as previously stated, is 9in. above ground level. Proceeded immediately to experiment plot, where the temperatures were recorded. The difference in temperatures in this case between the check plot and heated plot thermometers and the alarm thermometer being probably due partly to the difference in elevation of the plot thermometers which are 3ft. above ground level, whereas the alarm thermometer is 9in. above ground level:—12.45 a.m.—A, 38 degrees; B, 37.5 degrees; C, 37 degrees; D, 37 degrees; E, 37 degrees. 1.15 a.m.—A, 37 degrees; B, 36 degrees; C, 37 degrees; D, 36.5 degrees; E, 36.5 degrees. 1.45 a.m.—A, 37 degrees; B, 36 degrees; C, 37 degrees; D, 36 degrees; E, 36.5 degrees. 2.15 a.m.—A, 34.5 degrees; B, 34 degrees; C, 34 degrees; D, 34 degrees; E, 34 degrees. 2.45 a.m.—A, 32 degrees; B, 32 degrees; C, 31.5 degrees; D, 31.5 degrees; E, 32 degrees. All heaters available, namely, 127, were then lit with spreaders off. Time required for lighting by two men—one using torch and one removing lids and spreaders—was 25 minutes. Atmospheric conditions then were—calm, cloudless night, clear starlit sky. 3.15 a.m.—A, 32 degrees; B, 41 degrees; C, 41.5 degrees; D, 35 degrees; E, 35 degrees. When these readings were taken, heaters in the vicinity of thermometers B and C had been burning for approximately 25 minutes, whereas heaters in the vicinity of thermometers D and E had been burning less than 10 minutes. This was due to the fact that lighting which occupied 25 minutes was commenced at the northern end of the plot where thermometers B and C were situated, and lighting finished at the southern end of the plot alongside thermometers D and E. 3.45 a.m.—A, 31.5 degrees; B, 45 degrees; C, 37.5 degrees; D, 40.5 degrees; E, 40.5 degrees. All spreaders were then put on heaters to reduce rate of fuel consumption. 4.15 a.m.—A, 30 degrees; B, 40 degrees; C, 38 degrees; D, 38 degrees; E, 37.5 degrees. 4.45 a.m.—A, 29.5 degrees; B, 37 degrees; C, 37 degrees; D, 37 degrees; E, 36.5 degrees. 5.15 a.m.—A, 30 degrees; B, 36 degrees; C, 36 degrees; D, 35.5 degrees; E, 35.5 degrees. 5.45 a.m.—A, 30.5 degrees; B, 35.5 degrees; C, 36 degrees; D, 35.5 degrees; E, 35.5 degrees. 6.15 a.m.—A, 33 degrees; B, 37 degrees; C, 36.5 degrees; D, 37 degrees; E, 37 degrees. All heaters were extinguished at 6.30 a.m. For further record of this heating see accompanying graph, Fig. 7.

October 27—Alarm rang at 1.25 a.m., recording 34 degrees. A calm, clear, and starlight night. The following temperatures were recorded:—4.43 a.m.—A, 36 degrees; B, 35 degrees; C, 35 degrees; D, 35.5 degrees; E, 35 degrees. Thermometer readings were then taken half-hourly until sunrise. Shortly before dawn clouds appeared on the western horizon, moved by north to the north-east horizon; a light breeze from the north-east then developed and the sky became cloudy. At no time during the night did the temperature fall to 32 degrees.

SUMMARY OF TEMPERATURES RECORDED.

September 13th—Average temperature of unheated plot, 42 degrees. Average temperature of heated plot during 1 hour's heating (124 heaters with spreaders on all the time), 47.75 degrees.

September 21st—Average unheated, 38 degrees; heated average, 40.62 degrees. Time of heating not known, but less than 1 hour, spreaders on, 127 heaters.

September 24th—Average unheated, 32.66 degrees. Average heated plot, 34.8 degrees. Heated by 58 heaters for 1½ hours with spreaders on. Average of heated plot, exclusive of thermometer C where no heaters lit, 35.11 degrees.

October 26th—Average unheated temperatures, taken 3.15 a.m. to 5.45 a.m., equals 30.58 degrees. Average on heated plot, heated from 2.45 a.m. to 6.30 a.m., temperatures taken same times as unheated plot, 37.6 degrees; 127 heaters burning half to one hour with spreaders off, afterwards with spreaders on.

In connection with the above summary it should be borne in mind that the lowest temperature reached may do more damage to the crop in one half-hour than a low average will do over a long period.

Rate of Fuel Consumption.—It was found necessary to re-fuel some of the heaters, but not the majority, during the 3½ hours' burning on October 26th. It was found at daylight that some of the heaters contained an inch or more of water as an aftermath of the flood and rain previously referred to; this accounted for their tendency to boil over and to require re-fuelling after about three hours' burning. Re-fuelling can be carried on without extinguishing the heater by simply pouring in more fuel.

Economic Aspect of Orchard Heating.—It would appear from temperature records and orchardists' experience that what is required in this district is protection against frosts which may occur on two or three nights each spring, generally between the hours of, say, 2 a.m. and 6 a.m. From Californian and New Zealand experiments, and from this test, we can deduce that 80 to 100 5-quart Lard Pail heaters will be sufficient to maintain a temperature of 33 degrees under conditions of 27 to 28 degrees on the unheated area. In other words, we can expect to maintain an increase of 5 degrees which will be sufficient to counteract the damage done by general spring frosts. With spreaders off and a consequent greater fuel consumption a much higher range of increased temperature could doubtless be obtained. Heaters can now be obtained in Adelaide in lots of 150 at a cost of 1s. 9½d. each. They can be purchased cheaper in greater quantities, and I propose later to suggest modifications in design and manufacture which should also cheapen them. Fuel costs from 5d. to 6½d. per gallon, plus freight, when used for primary production and exempted from sales tax. The heaters are said to last for 10 years with care. Therefore, cost of heating one acre with 100 heaters would be—

	£	s.	d.
For one heating of four hours—annual rental value of 100 heaters ..	0	18	0
100galls. of fuel oil at 6d.	2	10	0
	<hr/>		
	3	8	0
For two heatings of four hours each—extra fuel	2	10	0
	<hr/>		
	£5	18	0

The foregoing paragraph gives an outline of the costs of orchard heating, as conducted in this experiment, without taking into account interest on the capital outlay and labor. It is proposed to deal with this aspect more fully in a later issue, together with a statement showing values of crop harvested from the heated and unheated plots. Many growers, however, who have watched the experiment with great interest are now of the opinion that it is economically possible and advisable to protect fruit crops from occasional spring frosts by adopting the practice of orchard heating.

FACTORS AFFECTING THE SEVERITY OF TAKE-ALL.

[By S. D. GARRETT, B.A., Assistant Plant Pathologist, Waite Agricultural Research Institute, University of Adelaide.]

1. THE IMPORTANCE OF SOIL MICRO-ORGANISMS.

In 1932 severe losses from take-all were experienced in South Australia, more especially on Eyre's Peninsula and in the Murray Mallee area. Many crops which right up to the time of heading promised an exceptionally good yield were rendered practically worthless by the sudden appearance of the disease in the whitehead stage. Until recently the conditions leading to the occurrence of take-all epidemics were little understood, but recent research work has led to a much clearer understanding of the factors concerned. Some of this work, bearing particularly on South Australian conditions, is described below.

FIELD OCCURRENCE OF TAKE-ALL.

Under South Australian conditions the first indications of take-all appear in August when the crop is 6in. to 1ft. in height, in the shape of small, generally circular patches, in which the plants are stunted, backward in growth, and yellowing off. The plants in these patches are usually dead before harvest, and weed growth becomes established. There is a gradation in size of affected wheat plants from those killed early, in the centre of the patch, to nearly full-grown plants at the edges, which go off with whiteheads. This suggests that there has been a slow extension of the fungus through the soil, during the growing period of the crop. Under certain seasonal conditions the patch form of take-all may not show up until the crop is heading in October. In this case the plants are not killed by the fungus until out in ear; instead of ripening off in the normal manner, the plants bleach off to a dead-white color, and the ears fail to fill out, hence the names "whiteheads" and "hay-die" applied to this stage of the disease. On the heavier classes of wheat soils, the disease usually does not develop further than these "primary patches." But on light sandy soils recently cleared from scrub, take-all may occur in certain seasons in a much more severe form. Whole paddocks of wheat, standing 4ft. high and just coming into ear, may rapidly bleach off with the disease, the affected plants not being in definite patches but scattered indiscriminately through the crop.

The primary patches of take-all are tentatively ascribed to the presence of *Ophiobolus mycelium* in the soil, which has survived from a preceding season on infected wheat stubble and on roots and haulms of infected pasture grasses. The date of appearance of such patches may be determined by the concentration of the infectious material in the soil, a comparatively heavy infection being necessary for the production of an early patch, or it may be influenced by the temperature and rainfall conditions during the winter. The number of such primary patches in any paddock will depend largely upon the previous treatment of the soil. If the crop has been sown on a fallow well-worked during the previous season, and on which rainfall was adequate, the early patches may be scarce or absent altogether. If, on the other hand, the fallow was neglected, or did not receive sufficient rainfall, or if the crop was sown on the stubble of a preceding crop affected by the disease, or immediately following a pasture of some years duration, then infectious material might be abundant in the soil, and the primary patches so numerous as to coalesce over large parts of the paddock. Crops sown after pasture seem to be especially liable to take-all, more particularly if the pasture has been of some years' standing.

Some pasture grasses are very susceptible to the disease, so that this is scarcely surprising. Finally, lack of consolidation of the soil also seems to favor the appearance of primary patches of take-all.

Another important source of infection in certain years may be the infected stem bases of cereals or grasses blown about in the wind. In a bad take-all year many crops and pasture paddocks suffer from the disease, and during the dry weather of the following summer the brittle stem bases of infected plants become loosened by stock or by wind and blow all over the farm, and on to clean fallow paddocks waiting to be sown with wheat in the autumn. Primary patches may thus occur in the next crop, even when the fungus had been eliminated from the soil by good fallowing methods, through reinfection by wind-blown material. In such a case, the take-all patches are concentrated chiefly round the edges of the crops. This is a commonplace experience of farmers. An example has already been given by Samuel (¹⁰), together with a photograph of infected pieces of barley grass stems picked up on fallows. Barley grass (*Hordeum murinum*) is probably the chief source of this wind-blown infection in the mallee areas. If it could be replaced by Wimmera rye grass, as advocated by Griffiths (⁴), this would undoubtedly constitute a considerable advance towards the control of take-all.

Whilst the primary patches thus appear to be to some extent within the control of the farmer, the occurrence of epidemics of whiteheads, involving whole paddocks of wheat in the heading stage, does not. The occurrence of such epidemics appears to be limited mainly to light sandy soils during the first 20-25 years after clearing, and to occur only in years in which the spring weather is dull and showery. It was discovered last year that the ascospores of the take-all fungus are ejected into the air during rainy weather in spring, from spore-cases formed on dead plants in the primary patches. The theory was advanced (⁹) that the epidemic whitehead stage of the disease usually resulted from late infection by these ascospores, dispersed over the paddocks by wind. The matter will be further discussed in Part 3 of this paper.

But an explanation had still to be found for the apparent limitation of extensive losses from whiteheads to light sandy soils in the first 20-25 years after clearing. To-day, such soils are mainly to be found in the Murray Mallee and West Coast areas in South Australia. On Yorke Peninsula, the soils of which are of the same general types, severe losses from take-all were experienced in the early years of settlement, but they are now comparatively rare. In the present paper, experiments are described, which suggest that this limitation of epidemic take-all to the light sandy soils is directly related to the lesser activity of the microbiological factor in such soils, or, in other words, that these soils are more susceptible to take-all because of the low numbers of soil bacteria present in them.

PREVIOUS WORK ON SOIL FACTORS.

The biological antagonism exerted by other soil organisms towards the cereal footrot fungi has been well established in recent years by Canadian research workers. The rapid deterioration of inoculum of the footrot fungi when added to soil, to which attention was first drawn by Simmonds (¹²), was attributed by Broadfoot (¹) to the operation of this factor. This suggestion was followed up by Sanford and Broadfoot (¹¹), who were able to show that infection of wheat seedlings by *Ophiobolus graminis* was completely suppressed by the antagonistic effect of a number of fungi and bacteria—not only by the living cultures, but also in many cases by their filtrates as well. Henry (⁸) showed that the growth of *Helminthosporium sativum* upon sterilised soil in small flasks might be completely inhibited by the addition of very small amounts of unsterilised soil, or by simultaneous inoculation with a number of other fungi and bacteria, so that no infection

resulted when wheat seeds were inoculated with the contents of the flasks in 5 in. pots. The work of McKinney and others on the soil temperature relations of *Ophiobolus graminis* is dealt with separately in Part 2 of this paper.

EXPERIMENTAL WORK.

Methods.

The soils used in these experiments were as follows:—

Gawler River Sand.—A river sand, very poor in organic matter and low in mineral salts. For some of the experiments the sand was treated with hydrochloric acid and well washed before use; in such cases the sand is described as "treated."

Glen Osmond Loam.—A red clay-loam, typical of the Adelaide Plains and Lower North wheat-growing soils.

Fig. 1.—Infection of a seedling root of wheat by *Ophiobolus graminis*.

(a) Surface view, showing the growth of the dark-colored runner hyphae of the fungus along the root.

(b) Longitudinal section, showing the connection between the dark-colored runner hyphae and the colorless infection hyphae which penetrate the cortex.

Murray Mallee Sandhill Soils.—Red brown sands.

Murray Mallee "Clay Flat" Soils.—Red loams.

Method of Estimating Infection.—The usual method employed for recording infection by cereal footrot fungi has been that of assigning infection-ratings by eye to the diseased seedlings after some four weeks' growth (McKinney (⁶)). For work upon the effect of soil micro-organisms, a more accurate measure of the activity of the take-all fungus under different experimental conditions was desired. A study was therefore made of the early stages of infection. The

progressive infection of wheat seminal roots by the fungus *Ophiobolus graminis* occurs through the growth of the fungal hyphae along the roots (Fig. 1, a). Under favorable conditions this is a rather rapid process, since it results from the growth along the outside of the roots of the dark-colored *runner hyphae* (the macrohyphae of Fellows⁽²⁾), which send in infection hyphae as they go to tap the food reserves of the root (Fig. 1, b). Invasion is by direct penetration, as described by Fellows, and may be accompanied by the formation of protuberances known as *lignitubers*, which appear to originate from the reaction of the host cell wall to penetration. The infection hyphae (Fellows' microphyphae) are colorless, and branch directly off the runner hyphae. (More rarely, colored branches of the runner hyphae themselves penetrate the cortex. Occasionally, too, the runner hyphae may travel one or two cells deep in the cortex, in the middle lamella at the junction of several cells). It will be realised that the progress of infection in the way described will be considerably more rapid than would be the advance of the fungus through a cellular tissue, owing to the absence of transverse cell-walls, better conditions of aeration, &c. Repeated microscopical examination has shown that infection never lags behind the apices of the runner hyphae for more than one or two cells.

The method adopted for the quantitative estimation of infection consisted simply in measurement of the rate of growth of the runner hyphae along the roots. In comparing the effect of two or more different soil conditions upon infection, wheat seeds were planted above small pieces of agar or cornmeal-sand inoculum of the fungus in the experimental soils to be compared. At intervals, pots were washed out, and the extent of infection along the roots recorded. Glass tumblers, of approximately 250c.c. capacity, were found very convenient for many laboratory experiments. Under such conditions, too, very good control could be obtained of soil temperature, moisture content, texture, and other factors difficult to adjust so accurately in larger pots in a greenhouse. By planting a sufficient number of such small pots in the first place, the progress of infection could be recorded weekly over a period of four weeks or more, although two readings, or only one, have generally been found sufficient for purposes of comparison.

The actual measurements were quickly and conveniently made under the binocular microscope, using an 8 × objective with an 8 × eye-piece. The root system of the plant was floated out in water in a petri-dish, and then viewed by reflected light from a reading lamp over a white opaque background. The runner hyphae were then easily visible under the 64 × magnification.

The roots were quickly followed down under the microscope until the limit of the runner hyphae was observed; they were then grasped with forceps at this point, and the distance to the point of inoculation (at the seed) conveniently read off against a scale drawn on the white background under the microscope stage. Restriction of measurements to the three oldest seminal roots was found to result in greater uniformity of results. These roots are all put out at approximately the same time, and under the same infection conditions. The fourth and fifth seminal roots are put out somewhat later, but they frequently showed a greater extent of infection (this is tentatively attributed to a decreased resistance of the cell-walls to penetration, since these roots are put out by a plant already laboring under the effects of infection). Finally, whenever possible, experiments were carried out at a temperature below 20°C. At the lower temperatures the advance of the runner hyphae along the roots was found to be very regular, and the limit of infection very easily perceived. At temperatures above 20°C, however, the behavior of the hyphae suggested a decrease in cell-wall resistance of the roots; a single hypha was frequently found quite a long way ahead of the remainder, and the runner hyphae even travelled occasionally one or two cells deep in the cortex—which made their detection, although by no means impossible, considerably more difficult.

It was found that the results obtained by this method corresponded with those obtained by means of the arbitrary infection ratings assigned by eye at a somewhat later stage, according to the method of McKinney (*). Whilst the method took rather longer for the recording of infection than that of McKinney, this disadvantage was offset by the greater accuracy of results, and by the fact that only comparatively small numbers of plants were necessary to establish experimental differences with statistical significance. Moreover, there was a saving in time, since many experiments could be concluded within a period of 2-3 weeks.

Experiment 1.—Growth of the Fungus Through Soil and Sand.

Glass tubes, 12in. long by 1in. internal diameter were employed; eight were filled with Glen Osmond soil and eight with treated Gawler River sand—each at approximately 50 per cent. saturation. After being filled to within some 2in. of either end, the tubes were plugged with cotton wool and divided into two lots, one of which was sterilised in the autoclave at 1 atm. pressure for 45 minutes. All the tubes were then inoculated at one end with *Ophiobolus graminis* growing on cornmeal-sand mixture, and placed in the incubator at 25°C. After 17 days, growth of the mycelium along the different tubes was as follows:—

	Mean. cms.
Soil, sterilised. 7.0, 7.5, 6.75, 7.25	7.13
Soil, not sterilised—0, 0, 0, 0	0
Sand, sterilised—5.75, 5.75, 5.75, 5.75	5.75
Sand, not sterilised—2.25, 1.5, 1.3, 0.8	1.5

In the sterilised soil growth of the mycelium was particularly dense and even, and easily visible to the naked eye; it was composed of fine, hyaline hyphae. In the sand the growth was sparse, and only to be observed with the aid of a hand lens; the hyphae were considerably coarser, and frequently dark-colored. In the non-sterilised soil no measurable growth had occurred.

Experiment 2.—Progress of Infection Down the Roots of Wheat Seedlings.

This experiment was conducted in glass tumblers. Six tumblers were filled with treated Gawler River sand, and six with Glen Osmond soil, both at approximately 50 per cent. saturation. Half of these were then sterilised in the autoclave for one and three-quarter hours at a pressure of one atmosphere. On cooling, the sterilised tumblers were placed under sterile bell jars. Inoculation and planting of the sterile tumblers was done in an enclosed chamber. A shallow layer of cornmeal-sand inoculum of the fungus was dropped on to the surface of the sterilised soil or sand and then the sterilised wheat seeds, which were finally covered with a layer of moist sterilised sand. The non-sterilised tumblers were planted in a similar manner, but without, of course, any special precautions. All tumblers were then placed in a glass-fronted incubator at 25°C. After 12 days, the plants were washed out for examination of the roots. Measurements of the progress of infection were as follows:—

Mean Extent of Infection along three oldest Seminal roots, in cms.	Mean.	Standard Error of Mean.
Sand, sterilised (12 plants)—4.6, 4.6, 4.1, 4.5, 4.6, 4.1, 4.5, 3.7, 4.7, 4.9, 4.5, 4.7	4.5	0.09
Sand, not sterilised (12 plants)—3.1, 2.7, 3.0, 2.8, 2.2, 2.7, 3.6, 3.5, 3.1, 1.9, 4.1, 4.7	3.1	0.21
Glen Osmond soil, sterilised—All roots completely killed before 3cm. long by vigorous growth of fungus extending 4.5 cm. through soil	4.5	—
Glen Osmond soil, not sterilised—Infection nil, or less than 0.5 cm.	0.5	—

In the sterilised Glen Osmond soil a dense and uniform growth of *Ophiobolus* mycelium had occurred in all three tumblers to a depth of 4.5cm. below the inoculum; the roots of the wheat seedlings had all been killed back at a depth of 3cm. or less. In the non-sterilised Glen Osmond soil, on the other hand, practically no progress of infection downwards from the inoculum had taken place; no measurements were recorded, but in no case had growth of the mycelium down the roots exceeded 0.5 cm. It would appear from these two experiments, then, that whilst sterilised Glen Osmond soil is a very favorable growth medium for *Ophiobolus graminis*, the unsterilised soil contains some factor which greatly checks the growth of the fungus. In unsterilised sand, on the other hand, the same factor, if present, only retards the rate of growth of the fungus down the roots by some 30 per cent.

Experiment 3.—The Progress of Infection Down the Roots of Wheat Seedlings in the Field.

Similar soil conditions to those in the last experiment were arranged in a field plot. Untreated Gawler River sand was used to fill a trench, 1ft. wide by 18in. deep and 10ft. long. Rows of wheat seeds were then planted in the sand, and in the adjacent soil. For inoculation, a pinch of cornmeal-sand inoculum of the fungus was dropped into each planting hole before the seed. At intervals, plants were dug up, washed free of soil, and the progress of infection down the roots recorded in the usual manner.

Mean Extent of Infection down three oldest Seminal Roots, in cms.	Mean.	Standard Error of Mean.
After 17 days—		
In soil (12 plants)—0.4, 0.0, 0.2, 1.1, 0.6, 0.0, 0.9, 0.2, 0.1, 0.5, 0.0, 0.0	0.3	0.1
In sand (11 plants)—3.3, 2.9, 3.0, 3.3, 3.4, 1.8, 2.8, 2.8, 1.2, 2.0, 2.5	2.6	0.2
Difference of Means, 2.3 ± 0.23		
After 24 days—		
In soil (12 plants)—0.6, 2.0, 0.0, 0.0, 0.0, 0.0, 2.3, 0.8, 0.7, 1.7, 0.9, 1.5	0.9	0.24
In sand (11 plants)—3.0, 5.8, 5.7, 4.2, 3.1, 5.7, 1.4, 1.8, 4.9, 2.5, 4.5	3.9	0.48
Difference of Means, 3.0 ± 0.53		

Microscopical examination of the infected roots from sand and soil, respectively, showed that whereas in sand the progress of infection was invariably of the rapid type due to runner hyphae growing down the outside of the root, in soil, on the other hand, the progress of infection was sometimes, though not always, limited to growth of the fungus inside the root. Growth inside the root is necessarily slower than that along the outside, owing to the presence of transverse cell walls, poorer conditions of aeration, &c. Thus in unsterilised soil there appeared to be some factor antagonistic to the growth of the runner hyphae of *Ophiobolus* along the outside of the roots.

Experiment 4.—A Comparison of Infection and Bacterial Numbers in some Murray Mallee Soils.

The soils selected for this experiment were taken from typical mallee sandhills and clay flats, respectively. Gawler River sand was also included in the series, for the purpose of comparison with the preceding experiments. The mallee sandhills are susceptible to the epidemic form of take-all, which occurs much less frequently on the clay flats. A sample of soil from the sandhill and another sample from the clay flat in the same paddock were taken from three Murray Mallee farms some distance apart. Two 4in. flower pots were filled with each soil, and all the pots were then well watered before planting, to allow the soil to settle

properly. Eight seeds were sown per pot; under each seed was placed a small block of the take-all fungus growing upon agar. The pots were maintained at a temperature of approximately 18°C., and one of each group was washed out at the end of 13 days. Mean infection in cms. for each soil is given below. At the same time, a sample of soil was taken from each of the pots, and counts of bacterial numbers were made by the plate method for each soil. These are also given below.

Soil.	Mean Infection in cms. after 13 Days.	Standard Error of Mean.	Bacterial Numbers in Millions per gm. of Dry Soil.	Standard Error of Mean.
Mallee clay flats—				
Yurgo	0.5	0.11	21.6	0.98
Karoonda	1.4	0.10	18.8	1.37
Wynarka	1.6	0.10	12.6	0.54
Mallee sandhills—				
Yurgo	1.9	0.14	14.8	0.80
Karoonda	2.3	0.11	8.4	0.62
Wynarka	2.5	0.12	7.2	0.72
Gawler River sand	2.0	0.18	7.5	1.20

Examination of the above results, also set out in diagrammatic form in Fig. 2 shows that (1) infection is consistently more rapid in the sandhill than in the clay flat soils; (2) the three clay flat soils (Yurgo, Karoonda, and Wynarka) fall into the same infection order as the three sandhill soils; (3) infection appears to be

INVERSE RELATION BETWEEN BACTERIAL NUMBERS AND SUSCEPTIBILITY TO TAKE-ALL IN SOME SOUTH AUSTRALIAN SOILS

Fig. 2.

inversely related to bacterial numbers in these soils. The infection figures recorded above, however, constitute only a partial record of the observed differences in infection between the sandhills and the clay flats. For, whereas in the sandhill soils the roots were thickly encrusted with runner hyphae over practically their whole infected length, in the clay flat soils the fungus might be represented by just a single straggling runner hypha for the greater part of the length recorded as infected, which would often appear quite healthy to the unaided eye.

Experiment 5.—The Effect of Adding Organic Matter to the Sand.

If the restriction to the growth and infection of *Ophiobolus graminis* in the heavier soils is due to the action of soil micro-organisms, it should be possible to modify the character of sand in this respect by the addition of organic matter. In the following experiment, therefore, untreated Gawler River sand was mixed with fowl manure in the proportion of 12 parts to 1 by weight, and filled into 6in. pots. Wheat seeds were planted with a small piece of agar inoculum immediately below as usual. Other pots were filled with sand alone, and planted with inoculated seeds in the same way. Measurements of the progress of infection down the roots in the two series were made after 20 days (the pots were kept in the open).

Mean Extent of Infection, in cms.	Mean.	Standard Error of Mean.
Sand alone (12 plants)—4.6, 4.3, 4.1, 4.0, 5.2, 4.4, 4.3, 4.7, 4.2, 3.7, 3.6, 4.2 ..	4.3	0.13
Sand + 1/12 fowl manure (12 plants)—1.4, 0.1, 3.3, 1.5, 1.1, 1.5, 1.5, 0.5, 0.5, 1.8, 0.3, 1.2 ..	1.2	0.25
Difference of Means, 3.1 ± 0.28		

The great retarding effect of fowl manure upon infection by the take-all fungus can once again be attributed to the increased activity of the soil micro-organisms. That it was not due to the extra nitrogen available to the plants appears unlikely from the results of the next experiment, which was running at the same time. It has been reported by Fellows ⁽³⁾ that liberal use of fowl manure gave good control of take-all in field tests conducted at the Kansas Agricultural Experiment Station.

Experiment 6.—Effect of the Vigor of the Plant on the Progress of Infection.

It was realised that any conclusions attributing differences in infection obtained in the above experiments chiefly to the action of biological antagonism might be justly criticised on the grounds that differences in the chemical and physical characteristics of the soils might well be reflected in differences in resistance of the plant roots to infection. Additional weight is lent to this criticism in view of the fact that sterilisation is known to be accompanied by chemical changes in the soil. It was therefore decided to compare the progress of infection along the roots of plants grown under four widely different conditions of nutrition, viz.:—

Full sunlight, with and without nutrient solution.

Poor diffuse light, with and without nutrient solution.

The nutrient solution employed was as follows:—

Ca(NO ₃) ₂	0.80 gm. per litre.
KNO ₃	0.30 "
KH ₂ PO ₄	0.20 "
MgSO ₄ ·7H ₂ O	0.20 "
KCl	0.20 "
FeCl ₃ ·6H ₂ O	0.025 "

The plants were grown in treated Gawler River sand; the supply of nutrient solution was certainly in excess of their requirements. The condition of poor diffuse light was obtained by the erection of a cardboard cylinder around the plant containers, all of which were sunk in an insulated tank, and covered with a mulch of granulated cork, so that there was no appreciable difference in soil temperature between the full sunlight and the poor diffuse light series. The plants were allowed to grow for 16 days before inoculation of the root-bases at the scutellar nodes. By this time, considerable differences in the size and character of the tops in the four series had appeared, and it was considered that any differences in resistance of the roots due to differences in nutrition should have had ample time to appear. In the full sunlight series, the addition of nutrient solution had already resulted in a very considerable increase in size of the plants, which were also of a much darker green colour; in the poor diffuse light series, all the plants, both with and without nutrient solution, were very poor and spindly. After 21 days, the plants were washed out and the progress of infection recorded.

Mean Extent of Infection, in cms.	Mean.	Standard Error of Mean.
Full sunlight, with nutrient solution (eight plants)—4.5, 3.4, 2.8, 5.3, 3.4, 4.3, 4.6, 4.8	4.0	0.31
Full sunlight, no nutrient solution (eight plants)—2.9, 2.8, 3.8, 3.8, 2.9, 3.9, 4.4, 4.4	3.6	0.26
Poor diffuse light, with nutrient solution (nine plants)—1.8, 2.7, 3.5, 3.7, 3.2, 2.8, 2.4, 2.8, 3.2	2.9	0.18
Poor diffuse light, no nutrient solution (five plants)—4.6, 2.7, 3.1, 3.7, 4.5 ..	3.7	0.37

From this experiment, then, it is clear that increased vigor of the plant from improved conditions of nutrition does not result in any increase of resistance in the seminal roots; at any rate, no such differences are reflected by the infection figures shown above. The differences in infection obtained in the preceding experiments would therefore appear to be attributable chiefly, if not entirely, to the operation of the micro-biological factor. Further work is in progress to demonstrate the antagonistic effect towards the take-all fungus of various types of bacteria from South Australian soils.

DISCUSSION.

In the experiments reported above satisfactory correlation has been obtained between the degree of infection obtained under laboratory conditions in a number of South Australian wheat soils, and the susceptibility of these soils in the field to epidemics of take-all. The experiments on soil sterilisation indicate that the micro-biological factor constitutes the important point of difference between the susceptible mallee sandhills on the one hand and the much less susceptible mallee-clay flats and the clay loams of the Adelaide Plains on the other. The mallee sandhill soils are characterised by a very low organic matter content, which would make for a poorer development of their microflora. Whilst counts of bacterial numbers in the mallee soils have indeed shown that infection increases with decrease of bacterial numbers, the degree of antagonism exerted towards *Ophiobolus graminis* by the soil bacteria must be influenced by other factors than that of mere numbers alone.

A similar correlation between infection experiments in the laboratory and the field incidence of take-all was reported by Moritz (*) for some German soils. The severity of take-all on the three main types of soil investigated by him—high-land soils, marsh soils, and Fehmann soils—was in the order 1.23; the values of

Moritz's "protective factor" in these three soils ran in the inverse order, 3.2.1. The "protective factor" gave a measure of the protection afforded to the wheat plant against take-all in any soil by the micro-organisms of that particular soil. It was obtained simply by dividing percentage infection in the sterile soil by that in the non-sterile soil. It is thus clear that the differences in incidence of take-all in these three German soil types are also to be attributed to the micro-biological factor.

Reference has already been made to the fact that the light sandy soils of the mallee areas, at first very susceptible to epidemics of take-all, later cease to suffer seriously from this disease, after some 25 to 30 years of cultivation. Thus, in the year 1917, Professor A. J. Perkins, Director of Agriculture in South Australia, remarked during the course of an address to the Conference of Upper Eyre's Peninsula Branches of the Agricultural Bureau (*), "Something like 25 years ago, this question (of take-all) was a very live one throughout Yorke Peninsula, which was then in comparatively early stages of settlement. Similarly, as soon as the settlement of the Murray Mallee and Pinnaroo district began, we had the same question cropping up, and again in Eyre's Peninsula on the lighter mallee lands I feel certain, however, that as you emerge from the pioneering stage, this disease will gradually disappear in the same way as it has practically disappeared on Yorke Peninsula." In the light of the experimental work reported in this paper, it is hard to resist the conclusion that the gradual decrease in the prevalence of take-all on these soils has been brought about by the increased activity of the soil microflora with cultivation.

Further studies will undoubtedly have to be made on the changes in the organic matter content and in the character and numbers of micro-organisms which take place with continued cultivation of South Australian soils under different systems

of rotation, &c. The evidence is now very strong that the micro-organisms present in a soil may exercise an exceedingly important controlling influence on take-all. If efforts are directed in mallee areas towards increasing the organic matter content of the lighter soils and therefore the population of soil micro-organisms, this will probably lead to a considerable reduction in the susceptibility of the land to take-all. It seems likely that the beneficial effect of sheep is due just as much, if not more, to their effect in changing the soil microflora as to their compacting influence on loose soils.

SUMMARY FOR PART I.

Epidemics of take-all in South Australia are practically confined to the light sandy soils of the mallee areas during the first 20-30 years of cultivation. On the older mallee soils, and on the heavier clay-loam soils of the Adelaide Plains and Lower North wheat-growing areas, severe attacks of take-all only occur under exceptional conditions, such as follow the ploughing in of infected grass or stubble.

Laboratory and field experiments have shown that infection of the roots of wheat seedlings by *Ophiobolus graminis* is very much more rapid in the lighter soils.

The difference in the rate of growth of the take-all fungus in these two classes of soils was completely eliminated by soil sterilisation, suggesting that the biological antagonism of micro-organisms in the heavier soils was responsible for the retarding of infection. This conclusion was supported by counts of bacterial numbers, which were found to be uniformly higher in the heavier soils, and by an experiment in which the addition of fowl manure to sand was found greatly to retard the progress of infection.

That the observed differences in infection in these two classes of soils were not due to differences in the resistance of the wheat plants themselves was proved by an experiment in which widely different conditions of nutrition were found to exert no effect on the progress of infection along the roots of wheat seedlings.

It is suggested that the gradual decrease in prevalence of take all upon the light sandy soils of the mallee areas with progress of cultivation is due chiefly to the increase in their organic content. Any measures which can be taken to hasten this process should therefore result in a decrease in the prevalence of take all.

A description is given of a quantitative method for the estimation of infection by *Ophiobolus graminis* under different soil conditions, by means of direct measurement of hyphal growth down the roots of wheat seedlings.

TEARING THEM OUT

In the regular job of the Monkey Grubber, in fact it was born to the work.

TREES and STUMPS, it matters not, they are born out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed. It develops the power of 250 men progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

Is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

DAIRY INDUSTRY PRICES.

ROYAL COMMISSION REPORT TO HIS EXCELLENCY THE GOVERNOR.

[A Royal Commission, consisting of Messrs. W. J. Dawkins (Chairman), Professor A. J. Perkins, and J. W. Wainwright, was appointed in January to inquire into and report upon the disparity between the prices paid by the consumer for dairy produce, the London parities of dairy produce, and the prices received by dairymen for milk and cream, the cause of such disparities, and the remedies therefor. The report is dated October 20th, 1933, and portion of it is quoted below. It is proposed to complete the report in subsequent issues.]

(Continued from Page 526, December issue.)

I. ADMINISTRATIVE MACHINERY.

In preceding pages a plan of operations has been outlined which, if adopted and adequately applied should do much towards improving the metropolitan milk supply, whilst protecting the interests of producers, vendors, and consumers alike. It is realised, however, that success in this matter will depend very much on the efficiency of the administrative machinery, and careful consideration has therefore been given to this question.

1. *Effectiveness of Control of Authority.*—It has become the settled conviction of most progressive communities that effective control over the milk supplies of large cities should be vested in a single authority with jurisdiction extending from the farms on which the milk is produced to the premises of each consumer; and it is generally admitted that when control ceases at the boundaries of a limited metropolitan area, its effectiveness is correspondingly weakened so soon as metropolitan requirements outgrow the economic possibilities of milk production within that metropolitan area; and it is something of this kind that seems within recent years to have affected the control of the milk supply of the Adelaide metropolitan area.

In the above connection the corresponding position in other large cities of the Commonwealth will be briefly glanced at; in Melbourne the State Department of Agriculture is sole controlling authority for both city and country milk supplies; provision for control may therefore be accepted to be adequate. In Sydney and Perth, milk boards control supplies from farm to consumer. In Brisbane control by a milk board with adequate powers has recently been recommended by a Committee of Inquiry, and it is anticipated that necessary legislation will be introduced in the coming Parliamentary Session.

Methods of control in Adelaide have already been described, but will be recalled here for purposes of comparison. Since 1909 control of the metropolitan milk supplies has been in the hands of the Metropolitan County District Board, which is presided over by the Lord Mayor, and over and above the control of milk has many other responsibilities thrown upon it. Apart from the distracting influence of varied responsibilities the main weakness of this type of control from the standpoint of milk is that its powers cease on the boundaries of the Metropolitan County District; and it follows that 50 per cent. of the milk consumed within the metropolitan area does not come under the control of the board until it crosses these boundaries. Beyond the latter, farms supplying milk to wholesale distributors or to milk vendors are supposed to be controlled by the Department of Agriculture; farms, on the other hand, the owners of which retail their own milk, are supposed

to be controlled by Local Boards of Health, if the latter function, and if not, by the Central Board of Health. But all milk intended for human consumption, whatever its origin, comes under the control of the Metropolitan County Board as soon as it enters the metropolitan area. This multiplicity of authorities controlling the destinies of milk has led to endless confusion, and has been partly responsible for lack of efficiency in the control of milk consumed within the metropolitan area and possibly in the country as well.

Hence, whatever might be the form ultimately given to the controlling authority, it is vitally important both to the success and the smooth working of the general scheme outlined in this report that such authority should have complete jurisdiction over milk production and transport, both within and without the Metropolitan County District, and obviously, too, over handling and distribution within the district.

2. Types of Controlling Authorities.—Your Commissioners have had under consideration three types of controlling authorities, namely:—

- (1) Control by the Metropolitan County Board with appropriate extension of powers.
- (2) Control by the Department of Agriculture.
- (3) Control by a special milk board.

(i.) *Control by the Metropolitan County Board.*—The opinion has already been expressed that control by the Metropolitan County Board has, of recent years, lacked in effectiveness for two main reasons, namely:—

- (1) The constitution of the board, and
- (2) Limited jurisdiction.

Of these two reasons the former cannot, and it is doubtful whether the latter could be remedied without introducing new disturbing elements.

If the Metropolitan County Board were to continue in control of the metropolitan milk supply under the proposed new scheme, its jurisdiction would have to be extended to all country farms licensed to supply the metropolis with milk. Any such extension, however, would lead to inevitable overlapping of corresponding functions of the Department of Agriculture, local authorities, and in some instances of the Central Board of Health.

The following facts should serve to illustrate the probable position:—

All country dairy farms licensed under the new scheme to forward whole-sale milk to the metropolis would, by the terms of their licences, be both suppliers of milk for human consumption and milk or cream for manufacturing purposes; nor would there be anything to prevent some of the owners from retailing milk in their immediate neighborhood. In extreme cases such activities would bring the unfortunate cowkeepers under the control of—

- (1) Metropolitan County Board;
- (2) The Department of Agriculture; and
- (3) According to circumstances, the local authorities or the Central Board of Health;

and each of these authorities would have its own set of regulations and its own inspectorial staff. It must be obvious that any such arrangement would be both uneconomic and costly to all concerned, and that it must lead to confusion and irritation in the minds of producers.

It is for reasons such as these that your Commissioners cannot see their way to recommending any extension to the existing powers of the Metropolitan County Board; and as, after a careful study of the whole question, they are convinced that radical changes in policy are essential in the interests of both producers and consumers alike, it is to be feared that the control of the milk supply of the metropolitan area will have to be placed in the hands of a differently constituted authority, on the sufficient grounds that the existing authority could not adapt itself to the change in policy.

(ii.) *Control by the Department of Agriculture.*—It has already been stated that the milk supply of Melbourne is under the control of the Victorian Department of Agriculture. An arrangement such as this presents certain obvious advantages, such as effective control of milk from the farm to the consumer by technically competent officers, and the disappearance of overlapping authorities, apart, perhaps, from health authorities with whom mutually satisfactory arrangements should always be possible. In principle, therefore, control of this character should be both technically and economically satisfactory, and its adoption in this State was urged by some witnesses before the Commission.

In South Australia at the present moment the authority of the Department of Agriculture over milk is limited by the Dairy Industry Act, 1928, to—

Every dairy farm outside the metropolitan area, from which milk is supplied in bulk to any factory, or to any milk vendor, whether for wholesale or retail trade; or the milk from which is used in manufacturing dairy produce.

It follows, therefore, that control of the metropolitan milk supply by the Department of Agriculture would imply no more than the inclusion of metropolitan dairy farms and retail milk trade generally within the ambit of its jurisdiction.

But there are objections to this mode of control which are perhaps less apparent at first sight than its obvious advantages. The first of these is probably that a public activity immediately affecting a section of the community only—those resident within the metropolitan area—and which custom would assign to local authorities concerned, would be administered and financed by a State Department. It is true that good reasons can be advanced for this delegation of authority and action. Reasons of economy, for instance, greater technical efficiency, elimination of overlapping, &c. It can be urged, too, that since unity of control is essential from the source of supply to the consumer, it would be necessary under purely local control to invest metropolitan authorities with powers over-riding those of established country local authorities, and such a policy might be difficult to justify.

Secondly, control by a State Department would usually imply one-man control, which could be justified when executive action only was in question, but not so well when matters of policy called for decisions. And if the recommendations made in this report for the better control of the metropolitan milk supply be carefully studied, it would soon be realised that, should these recommendations be adopted, wise policy decisions would, in the future, be of even greater importance than firm executive actions. The difficult claims of country and metropolitan milk will call for frequent readjustments. The fluctuating relationship of licences issued to the growing requirements of the community will call for careful consideration; and equally so the character and scope of supervision of producers, wholesale and retail vendors, shops, &c.; the periodic fixation of wholesale and retail prices; and many other delicate questions of policy involving intricate financial, economic, and technical problems, in the matter of which errors of judgment might easily lead to very serious consequences. It is for reasons such as these that your Commissioners are convinced that control by a corporate body, suitably constituted, should prove more satisfactory than control by a State Department.

(iii.) *Control by a Milk Board.*—It has already been pointed out that in Sydney and Perth the metropolitan milk supply is controlled by a milk board, and that in the near future the Brisbane supply will probably be under the same type of control. It is now suggested that control by a milk board would probably help to solve many of the difficulties of the Adelaide metropolitan milk supply. In this connection, however, much will depend upon the actual constitution of the board.

(a) *Type of Board Suggested by Milk Producers and Vendors.*—On various occasions in 1931 and 1932, deputations of milk producers and vendors waited upon the Chief Secretary and urged that the disabilities under which they labored

might be investigated and remedied, and, among other things, that the milk supply of the Adelaide metropolitan area be placed under the control of a milk board. In order to stress their earnestness, they went so far as to submit a detailed draft for legislation in the matter of the constitution of the board and the powers that should be vested in it.

The suggested board was to consist of five members, one of whom would be elected by country producers, one by metropolitan producers, one by retail milk vendors, one by metropolitan municipal and district councils to represent consumers, and one to be appointed by Government as chairman.

The powers to be vested in this board, on the other hand, were to be comprehensive and far-reaching. It was to have power to fix both wholesale and retail prices of milk; to vary such prices according to districts and quantities; to control all methods of handling and treating milk; to regulate the number of milk stores; to divide and subdivide milk distribution areas; to license all dairyfarmers and milk vendors; to collect all licence fees; to confine individual licences to well defined areas; to determine chemical and bacteriological standards of milk; to inspect all premises, and to examine all books and utensils wherever milk was handled or stored; to compel the production of business statements from dairyfarmers or milk vendors; to prohibit the sale of milk thought to be unwholesome; to require dairymen and vendors to keep prescribed books; to collect samples of milk for examination; to fix the hours during which retail milk might be sold; to cancel licences; to act as a local authority under the Dairy, Health, and Food and Drugs Act.

The document from which the above data have been summarised was forwarded by the Chief Secretary for consideration by the Commission. In addition, representatives of the original deputationists, together with other individual country and metropolitan producers and milk vendors, appeared before the Commission and stressed the pressing difficulties that beset them in their respective callings. That your Commissioners have not been unsympathetic, and that they recognised the justice of many of the claims brought before them is amply evidenced by many of the recommendations already made, but they regret that they feel quite unable to support the creation of a board on the lines desired by the deputationists. It would be wrong to place the control of an article of diet like milk, so liable to mishandling and contamination, so apt to be a vehicle of disease, and yet so essential to every member of the community, in the hands of a board, the majority of whose members was immediately interested in its sale.

3. *Type of Board recommended by the Commission.*—In the above connection the practice almost universally adopted by shareholders of vesting control of large undertakings in selected directorates, has in many countries been extended to specialised State undertakings. When this is done the major lines of policy are indicated in enabling Acts, and Cabinet Ministers are relieved of the irksomeness, and sometimes of the political difficulties, that attach to repeated decisions on minor matters of policy which are outside the usual functions of Government. The relative success or failure of such undertakings usually depends on the appropriateness of appointments to the board of control; and the latter again is frequently dependent upon the methods of appointment adopted. In this connection it can be stated in principle that apart from the question of personal competence of members, board control of any national activity cannot be expected to succeed unless members of the board can be depended upon to sink sectional bias and to adopt policy decisions based upon their due merits rather than those of vested interests. It has been urged by representatives of milk producers and retail vendors that the majority of the members of the milk board should be elected by their own constituents, from which, however, wholesale distributors appear to have been overlooked. In the opinion of your Commissioners a board

so constituted would from the national standpoint be bound to fail, and for the reasons that follow: its members would be unable to sink sectional bias; in the clash of their conflicting interests deadlocks and waste of time would be common, and the interests of the community might be overlooked; nor would appointment by election be any guarantee of personal fitness and competence in individual members.

It is certain that the milk board's prime duty of controlling adequate supplies of wholesome milk at reasonable retail rates would be jeopardised if its members were elected by conflicting sectional interests. The importance of the transactions involved may be gauged by the fact that the retail value of milk used within this area is approximately £400,000 per annum. Hence, it is strongly urged that the haphazard method of electing members of the board by sectional interests would be contrary to the public interest, and it is recommended that the board be constituted as follows:—

The Director of Agriculture (*ex officio*)—Chairman.

The Chairman of the Central Board of Health (*ex officio*).

A representative of the Metropolitan County Board.

Two members appointed by Government after consultation with organisations representing producers, and wholesale and retail distributors.

It is also recommended that the staff required to carry out the policy of the board should form part of the Department of Agriculture with the Chief Dairy Instructor as chief executive officer on the inspectorial and technical sides.

In making the above recommendations, special consideration has been given to the following points:—

(1) The necessity that varying degrees of competence should be represented on the board in order to deal effectively with difficult technical questions that will frequently come up for consideration. Hence the recommendation that the Director of Agriculture and the Chairman of the Central Board of Health should both be members of the milk board.

(2) It was considered that a representative of the Metropolitan County Board would adequately represent consumers.

(3) It was considered that the recommendation that the staff of the milk board form a section of the Department of Agriculture would lead to a maximum of economy in working expenses and to a minimum of overlapping.

(4) It was considered that adequate technical efficiency in staff work would be ensured if inspectors were under the immediate control of the Chief Dairy Instructor. This should render possible occasional assistance from District Instructors acting as *ex officio* milk board inspectors.

(5) It was considered essential to the smooth functioning of the milk board's work that the Director of Agriculture should be chairman of the board. Under this arrangement the possibly conflicting claims of a dual allegiance would be avoided as the Director would be in a position to issue instructions to officers both as Director of Agriculture and as chairman of the board.

(6) It was considered that the two remaining members of the milk board need not necessarily have had personal experience of the industry or the distributing trade although, other things being equal, it was admitted that men with such experience should be given preference over others. It was thought essential that these members should be able to take a broad national view of questions coming up for decision and that they should not look upon themselves as representatives of any particular section of the industry. It is nevertheless recognised that the earlier functioning of the board would be all the easier if from the outset it could be assured of the confidence of all concerned; hence, this aspect of the question should receive consideration, but not at the expense of the efficiency of the board.

4. *Inspectorial Staff of the Milk Board.*—It is a common although erroneous and dangerous opinion when technical matters are at issue, that any person of average intelligence should be competent to act as an inspector; and it can be added that this opinion is particularly dangerous when milk is concerned. Milk, in the course of its brief existence, is more than any other foodstuff exposed to contamination at so many points, and is so frequently controlled by those who do not realise the dangers of contamination, that it can be taken for granted that for one instance of official detection there will be 10 or more that escape detection. It follows, therefore, that in order to mitigate the evil the function of an inspector should be not only to detect breaches of regulations, but in addition to render their future occurrence unlikely, by endeavoring to appeal to the mind of the offender, and explaining to him the adequate reasons that should be behind every regulation. Hence, some degree of training must be looked upon as essential to the efficiency of every inspector.

In Victoria the Dairy Supervision Act, 1928, requires "that dairy supervisors should have *bona fide* practical experience in dairy farming and allied branches of agriculture and amongst animals."

In addition, candidates for appointment are required to sit for written and oral examinations, and undergo practical tests at Abattoirs relative to diseases in livestock. Appendix V. gives an account of the syllabus of the subjects in which candidates are examined.

In New South Wales the qualifications required by the milk board from its Supervisors are said to be similar in most respects to the standards required of health inspectors to local governing bodies, namely:—

- (1) Certificate of the Royal Sanitary Institute of London; or
- (2) Full Health Inspector's certificate at Sydney Technical College; or
- (3) Certificate of the Royal Sanitary Institute of Scotland; or
- (4) Certificate of the Sanitary Inspectors' Joint Examination Board of London.

In addition to the above qualifications, supervisors to the Sydney Milk Board must have an adequate knowledge of livestock and their diseases.

In the circumstances, it is recommended that should legislation be introduced towards giving effect to the recommendations of this report the board should have power to determine the qualifications required.

It is realised that upon the appointment of a milk board, some of the present inspectors under the Metropolitan County Board may become redundant. In such circumstances, these redundant officers should receive, in the opinion of your Commissioners, first consideration in the appointment of inspectors under the new board, subject however to the condition that they must satisfy the board that they are sufficiently well equipped for the purpose.

5. *Financial Arrangements.*—The work to be carried out by the milk board would be for the special benefit of a section of the community only, namely, the consumers of the metropolitan county district and those mainly concerned in the production and distribution of the milk required by these consumers. It follows that the administrative and general costs of the board should not be a charge upon the public purse, but should be directly defrayed by those on whose behalf the work would have been done. Towards this end it is recommended that:—

(1) A special fund be created to meet the expenses of the board, into which shall be paid all licence fees, fines, &c., together with a special contribution from the Metropolitan County Board of £2,000 per annum, increasing *pro rata* to increase in population of the Metropolitan County District.

(2) The first year or two's expenditure be met by means of a loan from the Treasury, repayable at interest within a reasonable period of years.

In support of the above recommendations it can be said that under the changed conditions that would obtain, should the general scheme outlined herein be adopted, the charges made for licence fees could be considerably increased without injury to anybody concerned. The progressive reduction in the numbers of licensed producers and of licensed vendors respectively should alone justify such increases. Indeed, many witnesses who appeared before the Commission advocated increases in licence fees as one of the measures that would help them out of their difficulties. On the other hand, under the scheme that is recommended, the Metropolitan County Board would be completely relieved of the control of the milk supply of the metropolitan area. The Commission was informed that the revenue of the board varied from £5,000 to £6,000 per annum, and that the greater portion of the time of its inspectors was concerned with milk. Hence, a metropolitan contribution of £2,000 per annum, increasing *pro rata* to increase in the population of the Metropolitan County District, is deemed a reasonable contribution of consumers of that area towards costs of improvements in their milk supply.

6. *Powers of the Milk Board.*—The extent of the chief powers of the board should be as follows:—

- (1) To issue licences for such purposes and subject to such conditions as it deems fit and proper.
- (2) To fix any fees by notice published in the *Government Gazette*.
- (3) To employ inspectors subject to the Public Service Act.
- (4) To take over the functions of the Central and Local Boards of Health and of the Department of Agriculture in controlling the production and distribution of milk in the Metropolitan County District.
- (5) To fix wholesale and retail prices of milk.
- (6) To regulate the milk supply of the metropolitan area.

J. RECOMMENDATIONS AS TO THE CONTROL OF THE MILK SUPPLY OF THE METROPOLITAN COUNTY DISTRICT.

I. A Controlling Metropolitan Milk Board.

It is recommended that special legislation be introduced to provide—

Recommendation 1.—That control over milk intended for human consumption in the Metropolitan County District shall be vested in a milk board with plenary jurisdiction over the farms upon which such milk would be produced, and over the milk itself from the farm to the consumer's door.

Recommendation 2.—That this milk board shall be constituted as follows:—

- (a) Director of Agriculture (*ex officio*), Chairman.
- (b) Chairman of the Central Board of Health (*ex officio*), member.
- (c) A representative of the Metropolitan County Board.
- (d) Two members selected and appointed by the Minister of Agriculture after consultation with representative associations of the dairy industry in all its phases.

Recommendation 3.—That a special fund shall be created to meet the expenses of the board, into which should be paid all licence fees, fines, &c., together with a special contribution from the Metropolitan County Board of £2,000 per annum, increasing *pro rata* to increase in population of the Metropolitan County District.

Recommendation 4.—That during the opening years—probably one or two years—the board's expenditure shall be met by means of a loan from the Treasury, repayable at interest within a reasonable period of years.

Recommendation 5.—That licensing fees shall be reviewed by the board and raised sufficiently to meet the board's expenditure concurrently with the Metropolitan County Board's contribution.

Recommendation 6.—That in the matter of vendors, licence fees shall be based upon the number of carts in use.

Recommendation 7.—That on the technical side the Chief Dairy Instructor in the Department of Agriculture shall be chief executive officer of the board, and that all District Dairy Instructors shall be *ex officio* inspectors of the board, but that their services shall be called upon in cases of emergency only.

Recommendation 8.—That the milk board shall take early steps towards determining what shall be the qualifications of an inspector under the board, and what measures shall be adopted to ascertain the fitness of applicants.

Recommendation 9.—That inspectors at present in the employ of the Metropolitan County Board, but who may become redundant when the milk board begins to function, may apply for appointment under the milk board on presentation of a clean discharge, and such application shall be accepted by the Public Service Commissioner, with the assent of the milk board, and subject to the certificate of its chief executive officer, to the effect that in the latter's opinion the applicants appear to be competent to carry out the duties of their office. All such appointments, however, shall be probationary in character only, in conformity with the current rule of new Public Service appointments.

II. Deduction of Metropolitan Milk Vendors to an Economic Number.

It is recommended—

Recommendation 10.—That subject to due protection of consumers' rights and requirements, the board shall take steps that will bring about a natural reduction of metropolitan milk vendors and increase in the mean delivery of individual rounds, and towards this end the following measures are recommended:

(a) Refusal to issue new licences until such time as metropolitan requirements should appear to render such issue desirable.

(b) Encouragement of legitimate vendors to buy out redundant vendors, and refusal to transfer licences to any but established vendors, excepting heirs or members of the licensee's family: Provided that such action shall cease as soon as the board is satisfied that the vendors have been sufficiently reduced.

(c) Encouragement of concentration of milk round by exchanges or sales.

(d) Insistence on scrupulous attention to hygiene and sanitation with a view to improvement of the milk supply and the gradual elimination of those unwilling or unable to comply with the milk board's requirements.

(e) Insistence on a buildings and appliances minimum for every vendor.

(f) Strict definition of a milk vehicle. Insistence of the presence on such vehicle in large letters of the owner's name, his residence, and the number of his licence.

(g) Stipulation that milk shops shall be limited to the sale of pasteurised milk bottled by licensed bottlers only.

(h) Refusal to recognise any licences issued after the first publication of this report.

(i) Abolition of the afternoon milk delivery.

(j) Power to refuse to issue licences if the board considered it not in the public interest to do so.

(k) Separate licensing of vendor on the one hand, and his premises on the other.

III. Adjustment between Metropolitan and Country Supplies of Milk, and Control of Pressure of Surplus Country Milk.

It is recommended—

Recommendation 11.—That with due regard to metropolitan milk requirements the board shall have power to determine:—

(a) That no dairy farm, whether situated in the country or in the Metropolitan County District, shall be allowed to supply milk for human consumption within the metropolitan area, unless specially licensed by the board so to do; and that

such licences shall be obligatory whether the milk be delivered directly to consumers or to vendors or to large wholesale firms for subsequent delivery to consumers.

(b) That such licences shall show, among other things, the name and situation of the farm concerned, the names and address of the licensee and the maximum number of cows the owner is allowed to carry under such licence; provided that such maxima on licensed farms may be varied on yearly renewal of the licences at the request of the licensees and with the consent of the board.

(c) That farm licences shall be refused unless the board were satisfied that the area used by the cowkeeper was adequate to the upkeep of the number of cows the latter proposed keeping; and in any circumstances, should the board decide that the land in question was situated within a well-defined residential area.

(d) That milk from licensed country dairy farms shall be adequately cooled immediately after being drawn from the cows, and shall not reach pasteurising depots at temperatures in excess of a minimum to be prescribed; provided that such milk may be sold as untreated milk if it reach its metropolitan destination at temperatures not higher than 40 degrees Fahrenheit, be immediately placed in refrigerators, and kept there until required for distribution.

(e) That all pasteurising depots handling household milk for distribution by their employees, or through the medium of vendors, shall be specially licensed for the purpose and shall receive milk from licensed dairy farms only; that such depots shall keep such records as the board may prescribe, and that their books and premises shall at all times be open to inspection by the board's officers.

(f) That with a view to spreading the advantages of the metropolitan price of milk over as wide a field as is economically possible, and at the same time providing ample means for meeting metropolitan probable requirements in months of low production, the quantities of milk sold by licensed country producers to pasteurising depots for human consumption shall in each case be limited to a fixed weekly quantity to be indicated upon the licence certificate of the supplier; and that such quantity shall not be exceeded except with the consent of the board.

(g) That on assuming authority, the board shall take immediate steps to ascertain the names of all cowkeepers, who in the 12 months immediately preceding publication of this report have been supplying the metropolitan area with milk, and of the weekly quantities of milk supplied by each cowkeeper. The board shall register the names of all such cowkeepers, and if so desired shall issue to them temporary permits to continue the supply of corresponding quantities of milk from their own farms for a period of six consecutive months. And all such cowkeepers shall pay to the board the value of one-half of the prescribed licence fees. At the end of these six months all those cowkeepers who are unable to comply with the requirements of the board shall be licensed as metropolitan suppliers, but those who are unable to do so will be refused a licence, unless good cause can be shown that they will be able to comply with these requirements within not more than three months from the expiry of the probationary six months.

(h) That purchasing pasteurising depots shall pay for the milk quota intended for human consumption at the metropolitan wholesale price prescribed by the board.

(i) That during a reasonable period pasteurising depots shall not sell or distribute for human consumption more than the aggregate quantity of milk they were licensed to receive for human consumption, and did receive and pay for at the prescribed metropolitan price during the currency of the same period and that adequate penalties be prescribed for any infringement of this regulation.

(j) That the board shall take early steps towards reviewing existing Board of Health regulations concerning milk, and in consultation with the health

authorities and the Department of Agriculture, agree upon such amendments and additions as may appear necessary to effective control of hygiene and sanitation on all licensed dairy farms, wherever situated, in licensed pasteurising depots, on the premises and conveyances of licensed vendors, and in all shops in which milk was sold.

(k) That in order to overcome the apparent lack of knowledge of the majority of those who usually handle milk, officers of the Department of Agriculture be asked to issue a printed statement setting out in detail the dangers to which milk is exposed from the time it leaves the cow's udder to the time it reaches the consumer; together with a description of the most approved methods of avoiding these dangers, and of rendering possible the delivery of the milk to the consumer in wholesome and sound condition.

IV. Measures of Price Control.

It is recommended—

Recommendation 12.—That in order to ensure to licensed country producers a reasonable price for milk, and to enable them to comply adequately with the board's hygienic and sanitary conditions, the board shall prescribe from time to time what shall be the minimum price payable for wholesale milk delivered in Adelaide and intended for human consumption, and corresponding parities at country pasteurising or receiving depots.

Recommendation 13.—That in order to assist towards the sale of household milk on a "quality" basis it shall be paid for on measured weights and on the basis of 4 per cent. butterfat, that is to say, that milk with a lower test will be paid for proportionally less, and milk with a higher test proportionally more.

Recommendation 14.—That in order to protect consumers against possible exploitation by vendors in combination, the board shall have power to prescribe, if necessary, a maximum retail price for milk delivered on the premises of consumers, and such maximum retail price shall correspond with the minimum wholesale price on a ratio to be determined.

V. Miscellaneous Recommendations.

It is recommended—

Recommendation 15.—That the board shall take steps to see that pasteurised milk shall be bottled in such a manner and under such conditions that purchasers of the same shall have the assurance that they are purchasing a sound natural product, free from contamination of any kind. Towards this end it is recommended—

(a) That no firm or individual shall be allowed to bottle milk for sale in the metropolitan area unless specially licensed to do so by the board.

(b) That such licences shall not be granted indiscriminately, but only to such as the board is satisfied are both willing and able to conform to the board's regulations on the subject.

(c) That such regulations shall prescribe, among other things, the bacterial count and sediment percentage of the milk to be bottled; the conditions under which it shall be pasteurised, chilled, and bottled; the maximum temperature at which the bottles shall be kept until delivered to the consumer; the type of bottle and distinctive brand to be used; and the marking of the capsule with the date of bottling in ink.

(d) That the proprietary rights of the bottler in his bottles should be given legal recognition and adequate protection against misuse.

(e) That neglect to comply both in the spirit and the letter to the board's regulations on the subject should render the offender liable to cancellation of his licence.

Recommendation 16.—That no cowkeeper, whether situated in the country or in the Metropolitan County District, shall make use of milking machines for drawing milk intended for human consumption unless specially licensed for the purpose by the milk board; that regulations shall be prepared indicating in detail precautions to be taken in the use of these machines; that cancellation of licence may follow any breach of such regulations: provided that a licence to use a milking machine may be refused by the board if it judges the applicant not to be a fit and proper person to use such a machine.

Recommendation 17.—That the standards prescribed by the Board of Health relatively to the composition and wholesomeness of milk intended for human consumption be reviewed, and, if thought advisable, extended on the lines suggested in this report.

Recommendation 18.—That the practice of collecting samples of milk intended for human consumption on farms, at pasteurising depots, and on vendors' carts for analysis and bacterial examination be made an essential part of all inspectorial work. Towards this end it is recommended for consideration—

(a) That the whole of the time of one inspector shall be devoted to this work.

(b) That special arrangements shall be made for adequate analysis and bacterial examination.

(c) That the results of such analyses and examinations with appropriate comments thereon shall be published regularly in the board's yearly reports.

Recommendation 19.—That the Act providing for the control of the metropolitan milk supply by a milk board shall empower the board to establish at opportune time "grades" of milk, and, among others, grade "A" milk which shall be the raw, untreated, milk from regularly tuberculin-tested herds, handled under strictest supervision and bottled on the farm. Towards this end it is recommended—

(a) That the board shall prepare very strict regulations on the subject, setting out in close detail the procedure to be followed in producing and handling grade "A" milk, and the standards to which it must conform.

(b) That dairyfarmers desirous of producing and selling grade "A" milk shall be specially licensed for the purpose after searching inquiry by the board into their personal fitness and the suitability of their premises for the purpose.

(c) That such licences shall not be transferable on sale or lease of the farm, or on death of the licensee, except with the consent of the board.

(d) That the licence fee shall be such as adequately to recoup the board for costs of special supervision.

Recommendation 20.—That power be given to the board to make such provision as it thinks fit for the control of blending and standardising of milk which is intended for human consumption.

DISSENT.

I dissent from the Commission's non-committal majority recommendation relative to the artificial standardisation of milk. I hold milk to be a natural and not a manufactured product from which nothing can be taken and nothing added. I believe, too, that human nature, being what it is, it is extremely dangerous to place in the hands of all and sundry the power to tamper with the composition of milk. I am strongly of the opinion that not only should artificial standardisation be discountenanced, but, in addition, that vigorous measures should be adopted with a view to stamping out the practice.

ARTHUR J. PERKINS.

(To be continued.)

[The Commission's report on the butter position will appear in the next issue.
—Ed.]

FRUIT CROP PROSPECTS IN SOUTH AUSTRALIA.

[Compiled on December 20th, 1933, by GEO. QUINN, Chief Horticultural Instructor.]

Apples.—The present season should have been a year of heavy crop in South Australia. The promise for a good all round yield was present in all districts up till the setting period when widespread but singularly patchy frosts occurred in most of the districts. The orchards which suffered have lost the great bulk of the crop, but those which missed the October frosts have an exceptionally fine showing, more particularly of the three leading export varieties, viz.:—Cleopatra, Jonathan, and Dunn's Seedling. The fruit is growing well, and up to the present is remarkably free from Black Spot fungus and Codlin Moth. It is somewhat premature to estimate the damage the latter may yet do, but generally, when November is passed in this State, and the fruit remains fairly free from Black Spot, the danger period has mostly been left behind. Unless something unusual occurs between now and harvest time this State should gather well over a million bushels of apples, and there should be no difficulty in filling the export quota suggested for the State at the Apple and Pear Export Council's meeting in November.

Pears.—The district reports indicate a somewhat light crop in most varieties, the Williams' Bon Chretien or "Duchess"—as it is locally termed—having the best showing. Frosts interfered with this fruit also. As the canners at present do not appear to be looking for the Williams' pears, no doubt an effort will be made to ship a good many thousands of cases to Europe.

Apricots.—In the valley of the Murray the crop is somewhat below average, and in the Barossa apricot orchards a magnificent showing has in many orchards been almost totally destroyed by the October frosts. The crop is good where no frosts occurred, but the aggregate for the State must result in only a medium yield, or 70 per cent. of the normal. The fruit which escaped frost is remarkably clean and well developed.

Cherries.—This fruit is not grown over a wide area in this State, but is usually of excellent quality. The harvesting season is now well advanced and the crop has proved an abundant one for nearly all varieties, the earlier softer kinds selling at ridiculously low prices. Owing to the absence of rainy and humid weather, little or no splitting, and rotting occurred this year.

Nectarines and Peaches.—The former are good, whilst the latter are showing from fair to good. The peaches grown are chiefly of dessert or drying freestone sorts, but a good sprinkling of trees of the better type of clingstones for canning purposes is coming into bearing.

Plums and Prunes.—The promise at blossoming time indicated good crops, but the ill effects of the frosts in most localities resulted in only very moderate yields now showing on the trees in all but a few favored spots. The prune crop on the whole will be a meagre one.

Citrus Fruits.—*Lemons* are showing for only a fair crop of winter main crop fruit. *Oranges* in most plantations and districts seem to have shed the newly formed fruits rather more freely than usual. It is still a trifle early to estimate the coming year's yields, but when the final drop has ceased, it is confidently believed quite a fair crop will be found on a majority of the trees. It is now recognised that the improved soil management and manuring methods which are being more widely adopted have a tendency to mitigate the heavy sheddings which formerly left the trees with scanty yields when the oranges reached maturity.

Figs.—In the Murray Valley the quantity of Smyrna drying figs is slowly increasing and the crop promises well. In the coastal areas where figs are widely grown for dessert and jam making, the trees are showing good promise for average crops.

Almonds.—There has been more activity in planting almond trees in this State during the past three or four years than for a long period. There has also been more interest displayed in attending to the older trees which have reached a bearing age, with the result that the yields are beginning to become more regular. This season there is from a medium to an average good promise of a crop in the various districts.

Walnuts.—The propagation of grafted trees of well proved named sorts has aroused new interest in this product, and many more trees have been planted, some of which are now coming into their first fruitings. At present the crops obtained are from the older irregular seedling sorts, and much of the fruit is destroyed each year by the Bacteriosis of the Walnut. The present promise is for a fair crop.

Quinces.—This much—but wrongly—despised fruit is grown almost without any attention, being usually planted alongside water courses in the hilly country. In consequence, the cropping is erratic, but seldom do the trees fail to yield more than the State's requirements. Reports indicate that a good yield is promising at present.

Grapes (drying sorts).—*Currants:* Excepting in parts of the coastal areas around Clare and in the Nuriootpa-Tanunda area where spring frosts devastated much of the vine growing acreage, this fruit is promising good yields. These losses, however, must seriously reduce the aggregate output of dried currants in South Australia in the coming harvest period. *Sultanas:* These are only a commercial success in the Murray Valley irrigated lands. The promise there is stated to be for a good average crop, but lighter than that of last season. A good deal of shedding of the newly set berries has occurred, but this will probably improve the size of the sample of fruit which remains on the bunches. *Gordos:* These are stated as showing for a crop above the average in the irrigated areas where they are more largely grown.

Wine Grapes.—In many areas in the Clare and Barossa districts the spring frosts decimated the grape crop, but in the central and southern and Murray Valley districts, the vines escaped serious injury. Taken on the whole, it is considered that the tonnage available this coming season must prove to be much below that of last season. Some of the heavier cropping sorts, such as the Doradillo, are not showing up for an average yield.

Bush and Small Fruits.—*Bush Currants:* The Black Currant is very sparsely grown in this State, but Red Currants are produced in sufficient quantities to meet domestic needs. The crop this season promises to fulfil this purpose. *Gooseberries* are stated to be cropping in from fair to good quantities sufficient for local requirements. *Strawberries:* Notwithstanding a long dry spell from the flowering onwards, the cool spring and early summer weather helped this crop, which is proving an excellent one. *Raspberries,* like Black Currants, are only produced in sufficient quantities to meet local needs. The crop this season is good. *Loganberries:* The blossoms on these plants were severely affected by the spring frosts in the principal districts, and the crops are poor.

Miscellaneous Fruits.—*Persimmons:* These are grown rather in excess of the local demand. Last season produced a heavy crop, the present promise is for only a fair return. *Tomatoes:* The glasshouse grown crops have been abundant during the season now drawing to a close. From reports received it appears the demand has been quite well maintained in interstate markets, but doubtlessly the competition from Western Australian fruit grown outdoors around Geraldton and shipped as deck cargo to Melbourne has kept prices down in that market over a portion of the ripening season of the Adelaide glasshouse grown tomatoes. The South Australian glasshouse tomato growers are exploring all the avenues in which reductions in cost, improvement of transport, and improved quality of the product may be achieved, and will not lightly yield to competitors in those markets which are lying closest to their doors.

SEED WHEAT FROM CROP COMPETITIONS.

In Wheat Competitions conducted in the undermentioned districts the following competitors exhibited crops which, in the opinion of the judge at the time of inspection, should produce grain suitable for seed purposes:—

Competition. Competitor. Address. Variety.

NORTHERN YORKE PENINSULA—

L. G. Northey, Kadina—Sword.
C. Rodda, Thrington—Sword.
F. P. Price, Paskeville—Sword.
G. E. Meier, Paskeville—Sword and King's White.
R. M. Yelland, Cunliffe—Daphne.
G. E. Rodda, Thrington—Sword.
R. S. Bussenschutt, Paskeville—Sword.
E. L. Yelland, Cunliffe—Waratah.
Yelland Bros., Cunliffe—Sword.

CENTRAL—

T. W. Day, Reeves Plain—Sword.
E. W. Day, Reeves Plain—Sword.
L. W. George, Wasleys—Sword and Ford.
R. Perry, Wasleys—Sword.
R. L. Lines, Wasleys—Sword.
C. R. and R. P. Currie, Wasleys—Sword.
W. K. Oliver, Wasleys—Nabawa.
A. M. Dawkins, Angle Vale—Nabaw.
A. W. Roediger, Gawler—Sword.
J. H. Dawkins, Gawler River—Sword.

BALAKLAVA—

J. D. Campbell, Baraba—Sword and Ford.
Harkness Bros., Owen—Sword.
J. A. Campbell, Stockyard Creek—Sword and Ford.
D. J. Wilson, Stockyard Creek—Ford.
L. C. Mills, Balaklava—Sword.
R. P. Anderson, Halbury—Sword.

*ALFRED—

A. C. Webb, Paruna—Ranee 4H, Sword.
A. A. Patterson, Paruna—Sultan.
E. M. Edwards, Paruna—Ranee 4H.
A. A. Marsh, Meribah—Sword.
W. Paull & Sons, Alawoona—Nabawa.

*ALBERT—

G. H. Sutherland, Copeville—Canberra.

BUXTON—

E. J. Beinke, Kimba—Waratah.
F. Newman, Kimba—Sword.
C. G. and G. W. Cant, Kimba—Sword.

JERVOIS—

D. C. McCallum, Rudall—Waratah.
J. C. Kobelt & Son, Darke's Peak—Waratah.

WESTERN—

L. O. Roberts, Port Pirie—Currawa.

LE HUNTE—

W. P. Bartley, Wudinna—Nabawa.

MID-NORTHERN—

A. Maitland, Rochester—Nabawa.
F. J. Pedler, Koolunga—Ranee, Sword, Carmichael's Eclipse, Mogul
Button Bros., Koolunga—Aussie, Ford, Nabawa.
H. S. and O. S. Freeman, Koolunga—Sword.
P. J. Saunders, Hoyleton—Sword.
Chapman Bros., Hoyleton—Sword, Ford.
Jas. Hay, Yacka—Sword.
J. and D. Teakle, Gulnare—Sword.
Higgins Bros., Georgetown—Free Gallipoli.
M. Smart and Sons, Gulnare—Sword.

Competition. Competitor. Address. Variety.

NORTHERN—

W. F. Wurst, Laura—Nabawa.
 W. D. Pearce, Gladstone—Sword.
 J. W. Prior, Gladstone—Nabawa.
 R. A. Bundle, Gladstone—Ford, Sword.
 H. C. Jaeschke, Wirrabara—Nabawa.
 W. M. Neate, Caltowie—Sword.
 F. H. Symonds, Caltowie—Sword.
 W. H. Adams and Sons, Caltowie—Sword, Waratah.
 Blessing Bros., Gladstone—Nabawa.
 W. S. Bennett, Gladstone—Ford.

FAR NORTH—

T. F. Orrock, Wepowie—Ranee 4H.
 J. G. Crocker, Wepowie—Ranee.
 W. G. Gregurke, Wepowie—Felix.
 D. J. Crocker, Box 56, Orroroo—Ranee.
 E. H. Hampel, Terka—Onas.

*CHANDOS—

A. J. Beelitz, Parrakie—Waratah.
 C. and L. Fischer, Pinnaroo—Robin.
 H. S. Angel, Pinnaroo—Robin.
 L. M. Symon, Pinnaroo—Ranee 4H.
 H. L. Badman, Pinnaroo—Sword.
 Young and Blacksell, Pinnaroo—Ranee 4H.
 Young and McInerney, Pinnaroo—Waratah.
 J. H. and C. H. Spratt, Lameroo—Gallipoli.
 A. J. A. Koch, Lameroo—Bencubbin.
 C. E. Koch, Lameroo—Sultan.
 J. L. Koch, Lameroo—Waratah.

MID-YORKE PENINSULA—

G. F. Pearce, Maitland—Ford.
 S. Heinrich, South Kilkerran—Gerralying.
 H. C. Schrapel, South Kilkerran—Ford.
 O. H. Heinrich, South Kilkerran—Ford.
 J. S. Henderson, Artherton—Ford.

SOUTHERN—

C. Brook, Woodchester—Nugget.
 J. M. Hudd, Hartley—Waratah.
 J. F. C. Paech, Callington—Nabawa.
 C. F. Altmann, Monarto South—Nabawa.
 E. E. Liebelt, Monarto South—Nabawa.
 L. M. Thiele, Monarto—Nabawa.
 Frahn Bros., Monarto—Nabawa.
 E., T., and L. Jaensch, Hartley—Nabawa, Bencubbin.
 A. B. Jaensch, Hartley—Nabawa.

MIDLAND DISTRICT—

F. D. Lake, Owen—Sword and Nabawa.
 W. H. Brown, Alma—Sword and Waratah.
 P. McD. Smyth, Salter's Springs—Sword and Ford.
 D. L. Clarke, Tarlee—Sword.
 A. T. Hill, Tarlee—Sword.
 G. Hazel, Kapunda—Gallipoli, Nugget, Ranee, and Ranee 4H.
 W. Parham, Hamilton—Nugget.
 Reg. Durdin, Buchanan—Sword.
 W. R. Durdin, Buchanan—Sword.
 W. Armstrong, Buchanan—Sword.
 L. V. Bell, Marrabel—Ranee and Clarence.
 L. J. Harvey, Hilltown—Turvey and Dan.
 J. Ross, Mintaro—Waratah and Gallipoli.
 R. and L. Blatchford, Mintaro—Sword.
 G. W. Woods, Mintaro—Gallipoli.
 A. S. Woods, Mintaro—Waratah.
 H. Schunke, Manoora—Gallipoli and Waratah.
 M. E. Glynn, Riverton—Sword.

MIDLAND DISTRICT—continued—

Competition. Competitor. Address. Variety.

C. H. J. Behn, Riverton—Ranee, Waratah, Florence, and Baringa.
 E. W. Williams, Tothill's Creek—Ranee and Gallipoli.
 F. Mahoney, Farrell's Flat—Clarence.
 G. Miller, Farrell's Flat—Bena.
 L. Martin, Farrell's Flat—Mogul and Sword.
 A. E. Crossing, Farrell's Flat—Gallipoli.
 S. Garrard, Farrell's Flat—Gallipoli.
 F. Coleman, Saddleworth—Nabawa, Waratah, Tuela x Ford, and Gallipoli.

FLINDERS—

R. Kain, Yeelanna—Waratah, Gallipoli.
 W. Watkins—Ford.

TATIARA—

Fisher Bros., Bordertown—Ranee and Gallipoli.
 H. C. M. Pilgrim, Wolseley—Gallipoli.
 E. J. Buckley, Bordertown—Gallipoli.
 J. Gall, Wolseley—Gallipoli.
 S. Pitcher, Bordertown—Ranee.
 W. Gill, Keith—Gallipoli.
 F. B. Milne, Bordertown—Gallipoli and Sword.
 R. H. Grosser, Wolseley—Gallipoli.
 D. R. Milne, Bordertown—Gallipoli.

*Owing to the quick ripening of the crops in these districts the judge states that grading will be necessary in these seed wheat crops to eliminate pinched grain.

OATS.

Mr. E. L. Orchard advises that he inspected oat crops on the farm of Mr. F. J. Pedler, Koolunga, and reported that crops of Guyra and Mulga oats were suitable for seed.

MIDLAND DISTRICT—

G. Hazel, Kapunda—Palestine.
 C. H. J. Behn, Riverton—Calcutta Cape and Imbros Island.
 F. Coleman, Saddleworth—Calcutta Cape.

WHEAT CROSSES AT ROSEWORTHY COLLEGE.

In a recent report to the Chairman of the Governing Council of Roseworthy Agricultural College, the Principal (Dr. A. R. Callaghan) stated that the 1933 programme of wheat crossing commenced on September 29th. Weather conditions on the whole were favorable, but the material available was not as complete as was desired.

The main objectives kept in mind in planning the crosses were, in order of importance:—

1. Improvement in the baking quality of commercial Australian wheats.
2. Increasing disease resistance of commercial varieties, thereby increasing yield.
3. Breeding for short strong straw.
4. Breeding for improved holding capacity in varieties which show a tendency to shatter.
5. To increase size and fullness of head and fill sterile spikelets.
6. Breeding for drought resistance.

Generally speaking, popular varieties were used in all crosses, though in a few instances, non-commercial varieties were used as the male parent with a special motive.

Under the column headed "Objective," the improvement to the female parent only is considered. For example, in the cross Nabawa x Florence, the objective is to obtain a wheat similar to Nabawa in performance but with the quality and bunt immunity of Florence. Such a wheat would therefore be resistant to Flaxsmut and have high yield.

The salient objectives only are mentioned. The main objective in the cross Gallipoli x Sword 4 x Dundee is baking quality, but it should also be possible to obtain a wheat from this cross with the resistance to disease and straw strength of Dundee.

SUNSHINE FARM IMPLEMENTS

SUNGRADE

Stump-Jump Reversible Disc Plough.

2 Furrow with 26in. Discs,
Pole, Neckyoke and 2 Horse bar.

Easy to operate. Light to pull.

Illustrated Leaflet, Prices, &c., on application.

H. V. McKAY'S Sunshine Farm Machinery

DISTRIBUTED FROM

95-97, NORTH TERRACE, ADELAIDE.

(H. V. McKAY MASSEY HARRIS PTY. LTD).

The following successful crosses were made.

Female Parent.	Male Parent.	Objective.
Ford	Dan	To increase flagsmut resistance of Ford and improve head.
Ford	Dundee	Combination of two wheats of moderately high quality and good disease resistance in an endeavor to combine complementary factors if such exist.
Ford	Baringa	To improve holding capacity of Ford and to strengthen straw.
Ford	Forel	To improve baking quality of Ford.
Ford	Heiti (D)	A wide cross made in an endeavor to obtain the drought resistance of a Durum in a Vulgare.
Nabawa	Florence	Improve quality and resistance to bunt.
Nabawa	Dan	Improve head of Nabawa.
Nabawa	Dundee	Baking quality and stronger straw.
Nabawa	Heiti (D)	Drought resistance.
Sword	Currawa	Improve head and straw.
Sword	Dundee	Baking quality and straw.
Sword	Pusa 4	Baking quality.
Sword	Palestina (D)	Drought resistance.
Florence	Dan	Resistance to flagsmut and larger head. Will also have high quality and bunt resistance.
Florence	Dundee	Quality cross also for stronger straw in Florence and non-shattering.
Waratah	Sword	Improve disease resistance and yield
Waratah	Dan	Flagsmut resistance.
Dan	Baringa	Improve straw and improve yield.
Dan	Forel	Baking quality.
Currawa	Florence	Baking quality and earliness. Bunt resistance.
Baringa	Finch	Baking quality.
Baringa	Duri	Baking quality.
Riverina	Dan	Flagsmut resistance and improved head.
Gallipoli x Waratah	4 Gullen	Baking quality.
Gallipoli x Sword	1 Dundee	Baking quality.
Gallipoli x Sword	Pusa 4	Baking quality.
Gallipoli x Sword	Nabawa	Flagsmut resistance.
Indian F x Canberra	5 Minflos	Baking quality.
Dundee	Dan	Flagsmut resistance.
Dundee	Caliph	Improve yield.
Dundee	Gullen	Baking quality and earliness.
Dundee	Pusa 4	Baking quality.
Dundee	Haurani (D)	Drought resistance.
Gluyas	Dundee	Baking quality and straw.
Ghurka	Minflos	Baking quality.
Hope	Nabawa	Baking quality (from female side).
Marquis	Comeback	Baking quality.
Marquis	Canimbla	Baking quality.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 1.—ST. JOHN'S WORT

(*Hypericum perforatum*, L., var. *angustifolium*, DC.).

A weed specimen from Nuriootpa, forwarded to the Agricultural College recently for purposes of identification, proved to be one of St. John's Wort, the narrower-leaved form (variety *angustifolium*) of the plant known to botanists as *Hypericum perforatum*, L. It was stated in the accompanying letter that the weed was new to the district, and had first appeared evidently from a chance seed on the roadside, whence it had spread into an adjoining paddock.

The appearance in a new district of a plant, known to be one of the worst weeds in the Commonwealth, serves to illustrate the importance of early recognition and prompt action in the case of definitely noxious weeds. While a farmer can hardly be expected to know every plant that has proved to be troublesome in the State, he should at least know the weeds growing on his own, and on adjoining, land, and be able to recognise, as a stranger, any new plant as soon as it appears. He should also be familiar with the appearance of those weeds which, on account of their known harmful properties, have been proclaimed noxious, either for the State or for the district in which he lives. The early recognition of such plants is obviously a matter of great importance. Many of them seed very freely and, if one such plant is allowed to form and disperse its seeds in a new locality, others are certain to appear, and the eradication becomes correspondingly more difficult and costly. If several generations have been permitted to grow and flourish before notice is taken of a weed, the problem of its effective control may then assume such proportions as to be quite beyond the financial powers of the owners of the land infested. When it is remembered that some weeds can so depreciate the value of land as to render it quite worthless for productive purposes, at least for many years to come, it will be realised how necessary it is to attack such invaders early, and to prevent their becoming established on new ground. As St. John's Wort has shown itself to be a weed of this type, it will be of advantage to select it as the subject for the first of a series of descriptive articles, written with the object of assisting farmers and others to become familiar with some of the more important weeds domiciled in South Australia.

Botanical Name and Classification.—Prior to the year 1928 all forms of St. John's Wort growing in Australia were believed to conform to the type of *Hypericum perforatum* found in Britain, and on the Continent of Europe. Doubt was expressed on this point, however, by Sir Arthur Hill, Director of the Royal Botanic Gardens, Kew, England. The Australian forms seemed to him to possess properties far more harmful than those in Britain, where St. John's Wort had never been regarded as a very bad weed. At his request specimens from New South Wales, Victoria, and South Australia, were sent to Kew for exact identification. It is now accepted that the forms of the Wort growing in Australia belong to a continental variety originally described by De Candolle as the variety *angustifolium* (literally "narrow-leaved"). The name *Hypericum* is of uncertain significance, and is derived from the Graeco-latin name of some unknown plant. The species name *perforatum* is due to the presence of small transparent oil glands, which gives to the leaves the appearance of being perforated with tiny holes when held up to the light. The leaves and flowers also bear a number of small dark-purple opaque dots. The name "St. John's Blood" has been applied to the plant on account of a red dye obtainable from the flowers.

Hypericum belongs to a family of plants, the family *Guttiferae* or *Hypericaceae*, most of whose representatives are tropical shrubs or trees. The genus *Hypericum* is exceptional in having a distribution mainly outside the tropics. Of the 200 species of the genus, two occur in this State, in addition to the introduced Wort, namely, *H. gramineum*, Forst. f., and *H. japonicum*, Thunb. Both are much smaller plants than *H. perforatum*.

Description of Plant.—St. John's Wort is a smooth perennial with a woody underground stem, or rhizome, from which there arise a number of erect shoots growing to a height of from 1 ft. to 3 ft. The aerial stems are often of a reddish color, and are somewhat compressed. In cross section they appear spindle-shaped, due to the presence of two opposite, and decurrent, longitudinal ridges. Lateral branching occurs mainly towards the upper parts of the plants, and is usually more developed in one plane, the branches curving gracefully upwards, and thus giving to the plants a characteristic flattened and corymbose appearance. The leaves are opposite, unstalked, and are mostly about $\frac{1}{2}$ in. long by about $\frac{1}{4}$ in. wide. They are oblong in shape, obtuse, entire, and paler-green on the underside. The leaves contain minute transparent oil-glands, and are dotted, also, with a few dark-purple opaque glands.

The flowers are large, about $\frac{1}{2}$ in. across, bright yellow in color, and are borne in terminal corymbose cymes. The calyx is divided, almost to the base, into five pointed lobes. The five petals are dotted along their margins with small dark-purple glands; they are at first yellow, but become brown when dry. The stamens are numerous, and are arranged in three bundles. There is a superior three-celled ovary, containing numerous ovules, and bearing three styles, each with a terminal stigma.

The fruit is a capsule containing many seeds, which are small, golden-brown in color, and pitted on their surfaces.

The plants are in flower from November, to February.

Means of Spreading.—Locally the plants spread to some extent by means of their underground stems. These grow more or less horizontally, and send up new aerial shoots at intervals. This habit of growth leads to the formation of very dense stands of the Wort in situations favorable to its growth.

But it is mainly by seed that the plant spreads to other localities. The seeds are formed in very great numbers, and are very small and light. Probably they are dispersed in the first instance by wind, though rain and flood may play a part in the process. By wind action seeds will doubtless be deposited in gradually diminishing numbers over a wide radius from an infested area. Hay and other crops, stacked or growing in the vicinity, are almost certain to contain seeds of the weed, and so provide a medium for distribution. Seeds will fall also on fallowed land and on roads, so that mud on the feet of grazing animals or birds is another means whereby seeds may be carried for great distances. It has also been suggested that the seed capsules, which are sticky, may adhere to the coats of animals. Bushfires may also facilitate seed dispersal. Though vast numbers of seeds are destroyed by a fire, the tremendous draught created must carry many seeds high into the air. In general it may be assumed that the higher the seeds rise the further they will be carried before being deposited on the ground.

Effects on Stock.—St. John's Wort is poisonous to stock, and its evil reputation as a weed is partly due to this circumstance. When eaten in quantity it causes a peculiar sensitiveness to light. If animals have been fed on the Wort and then exposed to strong sunlight for a prolonged period, the unpigmented areas of the skin become inflamed and ulcerated. In severe cases actual death may result. In addition the plant, when eaten, is stated to produce an effect on the central nervous system, causing severe mental depression in most cases, but occasionally intense mental excitement.

History in Australia.—It would be difficult to find a better—or a worse—example of the depreciation of the value of land by a weed than is afforded by the history of St. John's Wort in parts of Victoria and New South Wales. The plant was introduced and grown in a garden at Bright, in Victoria, on account of its numerous and showy yellow flowers. It escaped from cultivation and established

ST. JOHN'S WORT.
(*Hypericum perforatum* var. *angustifolium*).

itself on vacant land in the district. It took complete possession of the local racecourse, and so earned for itself the name of "Racecourse Weed." Here it began to produce seed in such prodigious quantities that hay and other crops in the vicinity were liberally contaminated with it. These fodder crops provided a medium for the distribution far and wide of a weed, which soon showed remarkable powers of growth and development in its new environment. Owing to its habit of forming aerial shoots from a perennial underground rootstock, it was soon found that, not only was St. John's Wort able to spread with amazing rapidity, but it formed so dense a growth, when once established, that it choked out practically everything else, and came to occupy large areas to the almost complete exclusion of any other type of herbage. Attempts to get rid of the pest by hoeing or cultivation proved futile; it was found impossible to avoid leaving fragments of the underground system behind—fragments which, by the subsequent development of new shoots, gave rise to an infestation as dense as before. Some idea of the seriousness of the pest may be formed when it is realised that the area covered by the weed in Victoria to-day is something like a quarter of a million acres; that in the Tumbarumba district of New South Wales some 6,000 acres are more or less densely infested; and that of some 13 shires in the latter State, and in which the Wort is a serious problem, one shire alone was stated in 1926 to be spending £1,200 annually solely on the eradication of St. John's Wort.

Fortunately for South Australia, local conditions do not appear to favor the growth of this plant to the same extent as in Victoria and New South Wales, preferring as it does elevated regions with a fairly high rainfall. The weed is believed to have been present in the Coromandel Valley for very nearly 50 years, and though it has been spreading slowly during that time, it has not so far shown any tendency to do so at an alarming rate. It would be unsafe to assume, however, that there is no need to take precautions against its spread into new districts, for there are certain parts of the Mount Lofty and Barossa Ranges where the weed might produce serious results if allowed to spread unhindered. It is worthy of note in this connection that, both in Victoria and New South Wales, the spread of the weed was slow at first. From the date of its introduction at Bright, about 1880, it took 25 years for the plant to occupy 10,000 acres of land; but during the next 10 or 11 years the acreage increased to about 184,000. During the three years from 1902 until 1905 the area of Crown Lands infested increased by about 33 per cent.; in the next 10 or 11 years there was an increase of nearly 4,000 per cent. Similarly at Tumbarumba, New South Wales, though the plant was first observed in the district about 1899, it was not until 1926 that its potentialities as a serious weed made themselves fully appreciated. Though the total area of land occupied by St. John's Wort in this State is probably not more than 2,000 acres, the plant is spreading slowly, and from time makes its appearance in new districts. It is by no means impossible that, in the absence of strict precautions against its spread, the weed might reveal itself to be capable of producing results almost as disastrous as in the two Eastern States.

Occurrence in South Australia.—It is exactly 30 years ago that St. John's Wort was first brought before the notice of the readers of this *Journal*. In the issue of January, 1904, there appeared a description of the plant by Mr. W. L. Summers, accompanied by a fine colored plate. With regard to its occurrence in this State Mr. Summers then wrote as follows:—

To my knowledge the only place in South Australia where this *Hypericum* is growing wild is along the Coromandel Valley, about nine miles from Adelaide. Commencing near the Blackwood Railway Station, the weed is plentiful on the main road, and on land on either side for a distance of about 2½ miles. In places it is very plentiful, covering patches several acres in area. I believe the weed was first noticed about 18 years ago in this locality.

At the time this was written, the area covered by the Wort in Victoria was estimated to be nearly 9,000 acres. It was shortly after this, from 1905 onwards, that the weed began to spread at so phenomenal a rate in that State. The attention of other States was naturally drawn to the occurrence, and, very largely as a result of it, St. John's Wort was proclaimed a noxious weed in South Australia. This was in August, 1911. In the *Journal of Agriculture* for September, 1911, there appeared another short account of the plant by Mr. Summers, together with an improved colored illustration, which is reproduced again in the present issue. To quote Mr. Summers once more:—

It (i.e., St. John's Wort) has been known to exist for fully 20 years in the Coromandel Valley, where it occupies a good many acres of pasture besides being in possession of the rough land along the roadsides. It apparently does not thrive except in land with a fair amount of moisture, and up to a few years ago had not been reported in this State outside the district referred to. During the past few years, however, specimens have been received from Port Lincoln, Meningie, and Klemzig (i.e., Gaza) while it is also steadily spreading both north and south of Coromandel Valley.

Calvert (1932) gives the areas affected in this State as follows:—Coromandel Valley to Bridgewater, 1,300-1,500 acres; Port Lincoln, 50-60 acres; and at Clare, Yankalilla, and Birdwood.

Methods of Eradication.—St. John's Wort is not usually troublesome on land which is regularly cultivated; it is on arable and pasture land, especially in hilly parts, that the weed is so serious a problem. Deep ploughing, followed by thorough and persistent cultivation, would doubtless bring it under control in places where such methods are practicable. The method of eradication to be adopted in a given case, however, will depend upon the particular circumstances, and especially upon the size of the area infested. Where this is very small, a single plant or a small patch of them, it may be possible to dig them out completely. Unfortunately the underground stems are very brittle, and it is difficult to remove them completely. Unless this is done the portions left behind will continue to grow. It is usually advisable, therefore, to make use of a chemical exterminator. In all cases the aerial parts should, if possible, be cut down as near as possible to the flowering stage, and then raked together and burned. The chemical should then be applied liberally to the bases of the shoots and adjacent soil. The advantage gained by this preliminary cutting is that it reduces the surface area to which the chemical has to be applied, and enables the latter to act more effectively upon the underground system and its developing shoots and buds. Whatever substance is used for this purpose, the important thing is to persevere. More than one application of a spray is almost invariably necessary, and in the case of deep-rooted weeds like St. John's Wort several may be required. The purpose of the treatment is to kill out the underground systems of the plants, and this is accomplished partly by direct poisoning and partly by starvation. The initial cutting weakens the underground parts, especially if it is done at the flowering stage, but they will still contain sufficient reserve food to produce another crop of shoots. Application of the poison at this stage will kill these new shoots, as well as portions of the rootstocks from which they develop. But there will still be some underground parts not destroyed. These must be prevented from adding to their depleted stocks of food, which, of course, they will do if they are allowed to display any green foliage to the sunlight. If, then, there is not sufficient poison in the soil to kill any subsequent growth, and if any new green shoots appear, another spraying will be necessary, since every green leaf exposed to the light serves to strengthen the underground system which the treatment aims at destroying. Where the patch

is small, it may be possible after spraying to cover the area completely with sheets of galvanized iron. This excludes light, and so assists the action of the poison.

Chemical Exterminators Used.—The following chemicals have all been used with satisfactory results:—

1. Sodium Arsenite.—This substance is extremely poisonous, and so can only be used where stock can be rigidly excluded from the area. The solution is made by mixing 1lb. of arsenic and 2lbs. of washing soda with 5galls. of water. This should be liberally sprayed on the plants and surrounding soil. After spraying, animals should not be allowed access to the area until rain has washed the poison into the ground.

2. Salt (Sodium Chloride).—Where arsenic cannot be used, fairly coarse salt is effective. The salt, which should not be too coarse, is heaped liberally round each plant, making sure that none is missed. The method is expensive, since it requires from 3 to 6 tons to the acre. The Victorian Department of Agriculture advises applying the salt in the form of a strong brine solution.

3. Sodium Chlorate.—This is applied as a spray, the solution being made by dissolving 1lb. of the chlorate in water so as to form 1gall. of solution. Owing to the danger of spontaneous combustion, care should be taken to prevent clothing, or boots, &c., from being wetted by the liquid. The danger can be lessened by adding the more deliquescent calcium chlorate to the solution.

Biological Control.—On the large scale, where hundreds or even thousands of acres are covered by the weed, it has been found possible to control St. John's Wort by growing trees, especially *Pinus radiata*. This has been done with success at Bright, where the old racecourse—once so heavily infested with the weed—is now covered with pines, and the weed is effectively under control. The same is being done at Tumarumba. The very dense shade produced by these trees when grown close together in plantations effectively excludes the light, and so prevents the growth of the Wort.

In certain areas it has been found possible to suppress St. John's Wort by growing Subterranean Clover as a smothering crop. This is possible, however, only where a particularly luxuriant growth of the clover is obtainable.

The problem of control by means of insect parasites has been taken up by the Division of Economic Entomology of the Council for Scientific and Industrial Research. Some very encouraging results have been obtained in the laboratories at Canberra with species of *Chrysomela* beetles, which feed almost exclusively on species of *Hypericum*. While similar results have not as yet been obtained in the field, the work shows promise of being ultimately successful.

BETTER QUALITY WHEAT.

[Correspondence on the subject of better quality wheat has passed between representatives of the flour trade and the Department of Agriculture. At a meeting of the Advisory Board of Agriculture, the Director of Agriculture pointed out that good milling wheats generally yielded lower crops than the poorer types of milling wheats, and unless advances on ordinary prices were paid for high-class milling wheats farmers would not be induced to make a change. Amongst the correspondence referred to is a report (dated May 6th, 1933) by Mr. S. R. Cowley, who visited the "East" on business connected with compressed yeast. The report deals with the flour trade in general, and the extract published below is a plea for better quality.]

For a considerable time Australia has been sending fairly considerable quantities of both wheat and flour to many parts of what we speak of as "The East," and in the China market—by far the greatest consumer of Australian flour—the price factor is the only factor. The reason Australia has had such large demands for both wheat and flour is merely because the price quoted has been in more than favorable competition with that of other countries, particularly Canada and the United States of America.

Information from reliable sources shows that enormous quantities of wheat and flour are being imported in increasing quantities from Canada and the United States of America into Japan and North China particularly. In lesser measure the same remark holds good for practically the whole of South China, French Indo-China, the Federated Malay States, and in the Dutch East Indies. In the immediate future imports of flour into the East from Canada and the United States of America will show much larger figures than those concerned in Australia would expect to find.

There must be a reason why Canada and the United States of America are able to send such substantial quantities of wheat and flour into the East notwithstanding the much more favorable price position of Australia. The only reason is the quality factor, which means that the average standard of both wheat and flour from Canada and the United States of America is higher than that of Australia. There is also a distinct margin in favor of Canada as regards having a better general standard of quality than that of the United States of America.

It is rumored in many parts of the East that a scheme has been co-opted to flood Eastern flour mills with Canadian and North American wheat, and alternatively to get the baking trade of the East to use only Canadian and United States of America flours.

A number of bakers were interviewed by Mr. Cowley, and demonstrations were conducted in bakehouses. Everywhere the view was held that Australian shipments of wheat and flour had not been of a consistently standardised quality as regards quality and content of gluten, moisture content, and color. The Eastern market is a specialised market, and will always be so. The whole of the East is a different world entirely from that which we in Australia know. The Eastern mind has never been prepared and never will be prepared to accept an irregular and unstandardised quality, whether in wheat, flour, or any other product. Until and unless Australia learns this lesson severely, then Canada and the United States of America, so far as wheat and flour consumption in the East is concerned, will continue to enjoy the lion's share of the market.

Australian shippers of wheat and shippers of flour must be prepared to guarantee to the East a reasonably consistent color and a guaranteed minimum gluten content and maximum moisture content. It is not an impossible thing to standardise these factors, though it will entail important re-arrangements in

milling practice as well as in control of the strains and varieties of wheat sown in Australia. Within the next 10 to 15 years those parts of the East which are now so quickly taking on the consumption of white bread products will have adopted those styles of fermentation which necessitate the use of quick processes of bread making, and also those processes which produce rich varieties of bread because of added ingredients such as shortening, sugar, and eggs. Nowhere throughout the East in the modern bakeries was any tendency to adopt long process doughs observed. This simple fact decides that the flour used shall be, if not a high gluten content, at least standardised gluten content. This gluten content may perhaps be not more than a fixed average of 11 per cent., but so long as it is a fixed guaranteed standard then bakers of the East would know just how to conduct their fermentations.

The longer Australia is able to continue the present favorable price factor for flour supplies to the East, and the quicker the Commonwealth arranges to standardise the quality of her shipments, the firmer will be the hold upon flour consumers of the East to be obliged to use Australian flour. The reason is simply that every particular type of flour demands a particular type of fermentation. Australian flour requires different treatment from the flour of Canada and the United States of America.

Recommendations and submissions are:—For immediate action to be taken through the aid of cereal chemists to strengthen and standardise the gluten content of Australian flour; to equalise the moisture content; to see that the routine procedure of the mills that seek this trade conform to the requirements of the Eastern markets; to devise methods and formulae suitable for the fermentation of the various types of doughs as applied to conditions throughout the East; to send through the East a competent commercial milling ambassador accompanied by a skilled baking technician. It has been definitely arranged for skilled technicians from Canada and the United States of America to visit all parts of the East and demonstrate the use of their flours. In addition to this, competent technical officers have for at least two years been touring the East for the purpose of demonstrating the advantage of Canadian and United States of America wheats. Whilst climatic conditions associated with Canada and North America tend to give a permanent variety of high gluten content in the wheats, the deciding factor in the use of the resulting flour is not so much high gluten content as uniform gluten content. Methods of fermentation suitable for making high-class bread products can quite successfully be devised for flour of an average gluten content of, say, 10.5 per cent. to 11.5 per cent., or thereabouts. Bakers throughout the East—except in Japan—are chiefly composed of Chinese. All look for very

white products in their bakeries, as well as volume of bulk. It is this trait in the Eastern mind which has been taken advantage of by Canada and the United States of America. Important milling concerns have permanent men touring the whole of the East amongst bakers and merchants for the sale of their flour, and they always give definite grades with guaranteed gluten and moisture content for the respective classes of goods for which their flours are suitable.

It will be found upon careful testing that in normal seasons Australian flours could be standardised to a definitely higher gluten content than the average of the United States of America soft wheat flours. Therefore, by reason of the lower price quoted by Australian millers it is easily within the reach of Australian millers to train their Eastern customers in the proper use of Australian flour, thus securing permanent customers. There should then be no difficulty to earmark a certain percentage of the Commonwealth high gluten wheats to combat the trade of the Canadian higher gluten wheats and flours.

It was rather interesting to hear in Hong Kong that there had been no fixed ratio of price between the soft wheat flours and the hard wheat flours of Canada and the United States of America, and that it has frequently happened that the soft wheat flours have been higher in price than the hard wheat flours of the high gluten content.

There are several brands of the United States of America flours which regularly command as much as 20 cents per sack of 50lbs. higher price than a similar grade of flour from both the United States of America and Canada, and this higher price is obtained solely upon the simple fact that the milling firms under certain brands send only a definite grade of flour. In this respect the Chinese market differs from any other part of the East, so that *uniform quality and/or standard quality under a reputable name or brand commands respect in the Chinese market*. As one proof of this the Double Star brand of the United States of America origin which was first sold at as low as 15 cents to 20 cents per 50-lb. sack below ordinary brands has gradually worked up to a position where it now commands 10 cents and higher above all others, and the demand for this favorite brand is increasing in volume. It must be remembered that both China and Japan want our wheat and flour, but it is folly to send poor and indifferent grades of wheat and flour, because the Eastern peoples are not fools, and "anything" will not do for them. They are perfectly alert to what they are buying.

Wheat is still grown to-day throughout Australia for its capacity to yield bushels per acre rather than for its suitability for bread making. It is significant in this connection that New Zealand wheatgrowers, millers, and bakers have recently unanimously decided to recommend the New Zealand Cabinet to continue for a further period of five years the excellent work conducted under the Department of Scientific and Industrial Research.

Much of the trade in flour in New Zealand lost by Australia to Canada has been due to the lack of uniformity in the quality of the shipments. As a result of this lack of uniformity New Zealand bakers turned their attention to Canadian wheat. The result has been that New Zealand bakers and millers will not easily, even for price, revert to their former large use of Australian wheat and flour until such time that Australia can deliver more uniform quality. In addition to this, New Zealand, through its research scheme, has eliminated through the control of the field officers of the Agricultural Department many wheats which were unsuitable for bread making though prolific yielders of bushels per acre. Wheat-growers have happily co-ordinated with the millers and bakers, and with the aid of the Canadian cerealists engaged under the Wheat Research Institute millers have been able to devise methods of controlling their grists which give greater standardisation.

REGISTERED EARMARKS OR FIREBRANDS FOR SHEEP.

[Until recently there was no legislation in this State dealing with the registration of earmarks for sheep. Under the Brands Act, 1933, it is now necessary to register, and in the accompanying notes the Registrar of Brands (Mr. H. O. Laurenti) draws attention to the provisions of that Act in relation to earmarks and firebrands. The text of sections of the Act dealing with the subject is also quoted below.]

1. Every earmark or firebrand shall be registered in respect of a run of which the person applying for registration is the proprietor; and shall be used by such person only so long as he is the proprietor of such run. Upon ceasing to be the proprietor as aforesaid the registration of such earmark or firebrand shall be deemed to be cancelled: Provided that the registration may be transferred by any such proprietor to his successor as proprietor.

2. The registration of an earmark or firebrand shall entitle the person by whom it is registered to the exclusive use thereof within the sheep brands district within which the said run is situated.

3. Every registered earmark shall, in the case of male sheep, be placed on the off ear, and in the case of female sheep, be placed on the near ear.

4. No person shall place any registered earmark or firebrand on any sheep except in the position determined by the Registrar and stated on the certificate of registration.

5. If any sheep has been earmarked with a registered earmark, no person shall place any other earmark on such sheep on the ear upon which such sheep is earmarked as aforesaid: Provided that nothing in this section shall apply to the placing of a registered tattoo mark or a registered stud-stock brand on the ear of any sheep.

6. No earmark other than a slit shall be made on sheep except with pliers.

7. No earmark shall exceed $\frac{3}{4}$ in. in length or $\frac{1}{2}$ in. in width or diameter unless such earmark is a slit, which may be $1\frac{1}{2}$ in. in length from the tip of the ear.

8. In no case shall an earmark be made by means of a crop. "Crop" means a straight cut taking off any portion of the ear.

9. Subject to paragraphs 6, 7, and 8, any owner of a registered paint brand or tattoo mark for sheep may mark his sheep with any earmarks which he thinks proper, and may also attach tags to the backs of the ears of his sheep, but no such owner shall make any such mark or attach any tag to the off ear of any male sheep or to the near ear of any female sheep.

10. It is important that the Registrar of Brands be immediately advised of any alteration of run or of postal address.

LEGISLATION AFFECTING CATTLE AND SHEEP EARMARKS.

BRANDS ACT, 1933, No. 2117.

Section 60.—(1) No earmark other than a slit shall be made on any cattle or sheep except with pliers.

(2) A distinctive mark shall be made only as indicated by the registrar on the certificate of registration.

(3) In the case of cattle not more than one-third of the ear shall be affected by the making of any earmark thereon.

(4) In the case of sheep, no earmark shall exceed three-quarters of an inch in length or half an inch in width or diameter, unless such earmark is a slit, which may be one inch and a quarter in length from the tip of the ear.

(5) In no case, either of cattle or sheep shall an earmark be made by means of a crop.

(6) In the case of cattle, if any registered earmark is placed on the ear of any such cattle, no further earmark, mark, cut, or crop shall be placed on either ear of such cattle: Provided that this subsection shall not apply to anything done before the passing of this Act.

Section 38.—If any sheep has been earmarked with a registered earmark, no person shall place any other earmark on such sheep on the ear upon which such sheep is earmarked as aforesaid: Provided that nothing in this section shall apply to the placing of a registered tattoo mark or a registered stud-stock brand on the ear of any sheep.

Definition of "Crop".—"Crop" means a straight cut taking off any portion of the ear.

Section 69.—Any person who—

(d) marks, or assists in marking, or causes, authorises, or suffers to be marked, any cattle or sheep on the ear in any manner contrary to the provisions of section 38 or 60, or by cutting off part of the dewlap; or

(e) has in his possession any cattle or sheep with its ear marked contrary to the provisions of sections 38 or 60, or, in the case of cattle, with any part of the dewlap cut off; or

(f) marks or cuts the ear of any cattle whereon a distinctive mark has already been made;

shall be guilty of an offence, and liable to a penalty of not less than two pounds and not more than one hundred pounds, or shall be liable to be imprisoned for any term not exceeding six months:

Provided that it shall be a defence in any proceedings under subdivision (e) of this section if the defendant satisfies the court that the ear was marked or dewlap cut off by some person other than the defendant and without his knowledge or authority, express or implied.

Section 70.—(e) Any person who introduces into the State from any other State of the Commonwealth of Australia any cattle or sheep with its ear marked contrary to the provisions of section 60 or, in the case of cattle, with any part of the dewlap cut off; shall be guilty of an offence, and liable to a penalty, which, except where a different penalty is expressly prescribed by this Act, shall be not more than twenty-five pounds, or shall be liable to be imprisoned for any term not exceeding three months.

Section 71.—No person shall be deemed guilty of an offence against paragraph (e) of section 70 if the cattle or sheep introduced by that person contrary to the provisions of the said paragraph are, within ten days after introduction into the State, slaughtered at the Metropolitan Abattoirs established under the Metropolitan Abattoirs Act, 1908: Provided that the Minister may with respect to any sheep or cattle extend the time for slaughter mentioned in this section, and may approve of some other place than the said Metropolitan Abattoirs as the place for slaughter, or may approve of the keeping of the sheep or cattle in the State for any period he thinks fit.

THE OCCURRENCE OF EELWORMS ON THE ROOTS OF CERTAIN GRASSES.

[By W. C. JOHNSTON, R.D.A., Agricultural Instructor.]

INTRODUCTION.

Eelworms are known to be serious pests to many types of plants in the Old World and America, as well as here, but in most cases they have been observed on the roots of cultivated plants.

In South Australia their occurrence has been recorded as a pest with cereals only, but it is now proposed to show that they become apparent on the roots of at least three different species of grass.

No attempt has been made to classify the worm, but it has been assumed that it is the same species as that which attacks cereals in this State. It is proposed to deal with them under three headings:—

- I. History of the pest in this State.
- II. Its occurrence on the roots of naturalised grasses.
- III. Its occurrence on the roots of a grass sown for its seed.

I.

Davidson discussed the presence of Eelworms in South Australia in the November issue of the *Journal of Agriculture*, 1930, when he dealt at some length with the disease as it affects cereal crops. He further reviews crops liable to be attacked in other parts of the world, but makes no reference to the pest being found on any other than cultivated plants.

Head Office: MELBOURNE.

Hickenbotham, in the same issue of the above *Journal*, discusses the pest as it affects cereal crops in the district immediately surrounding the Roseworthy College, but makes no reference to it being found on the roots of other graminaceous plants which are to be found in close proximity to the affected crop or as weeds in the stubble of an affected cereal crop.

II.

In the course of investigating the serious "no-growth" of wheat and oats in the Bute district, it was decided that the chief cause of the trouble was the very heavy infestation of Eelworms on the roots of the plants. The worms were easily visible at the time of inspection, as the females were then in the cyst stage.

Many of the plants taken up for observation were found to be literally covered with cysts; their prevalence led to the discussion as to whether they attacked the naturally occurring grasses. As Barley Grass was the most common naturalised species a critical examination of its roots was made, and in almost every case was evidence of infection forthcoming. This being so it was decided to make a further search on the roots of Sterile Brome—a grass known in this area as Sland's Grass—and it became evident that this species was not immune from attack.

During the course of the day evidence of the pest attacking these two grasses could be established in almost every case where it was actively looked for, which, in effect, meant that it was found in fields some miles apart. Whether the grasses were taken from a crop where it was a weed or from a stubble the female cysts could be easily found.

In this season there are no outward symptoms to suggest that these grasses are being attacked by the pest, either when they are in a crop or when in stubble. There is a theory amongst the farmers that Barley Grass seldom makes rapid growth on the stubble of a crop which has been a failure through identical symptoms, as shown by the crops this season. If this is so it may reasonably be assumed that the poor growth of Barley Grass on stubbles is largely due to the ravages of Eelworms—a fact that must not be lost sight of when attempting to control the pest.

III.

The sowing of Canary Grass (*Phalaris canariensis*) as a crop for the production of its seed is a rural activity which has gained considerable popularity in the last few seasons, and it was during an inspection of an area sown to this plant that small patches exhibiting similar symptoms to Eelworm attack in cereals were observed. In this case careful examination failed to locate the female cysts, although the roots had all the characters of being infested. However, similar patches were noted in another field of the grass, and an investigation revealed the presence of numbers of cysts on the root, thus establishing the fact that this crop is not immune from the ravages of Eelworms.

CONCLUSIONS.

(1) Eelworms are found to attack at least two naturalised grasses in South Australia.

(2) The pest attacks these plants whether in stubble land or as a weed in a crop.

(3) The pest may prove to be of economic importance in the production of Canary Seed in this State.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird

No. 5 Test.—Morning—2ozs. wheat per bird.

Evening—2ozs. wheat per bird.

Greenfeed in season

The following are the numbers of eggs laid by each pen from April 1st, 1933, to December 31st, 1933

METROPOLITAN ABATTOIRS, ADELAIDE

MANUFACTURERS OF

Meat Meal for Pigs

Read Report of Trials made by PROF. PERKINS,
Journal of Agriculture, January and July, 1921.

Meat Meal for Poultry

For full information on above write to

NOTE.—Only first grade eggs are shown above.

DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED reported on January 3rd, 1934.

BUTTER.—Production of butter for the month of December showed a further decline but there is still a substantial quantity being produced over and above local requirements and consequently export to London will continue for some time. Realisations in London have been most disappointing as the market declined rapidly during the month. On December 1st values ruling in London for choicest quality butter were 72s. per cwt., but at the end of the month only 64s. to 68s. per cwt. were obtainable. This decline in values was most disheartening to manufacturers and producers as it necessitated a lowering in the purchase price of butter-fat. Owing to the State equalisation, however, local values were maintained (choicest creamy fresh butter in bulk, 1s. 0½d.; prints and delivery extra (these prices are subject to the stabilisation levies); store and collectors, 4d. to 4½d. per pound at store door, less usual selling charges.

EGGS.—Although exporting continued throughout the month, the quantities shipped overseas were considerably less than for the month of November, but this is to be expected because of the warmer weather. A large percentage of the eggs arrive in a heat affected condition and consequently are not suitable for export overseas. The quantity of poor quality eggs was very pronounced in the latter part of the month and this resulted in prices of the ordinary eggs being reduced ½d. per dozen. Ordinary country eggs, hen or duck, 3½d. per dozen; selected eggs, 1½ozs and over, 6½d. to 7½d. per dozen.

CHEESE.—Owing to the better demand on the local market and the seasonal reduction in production, the quantity packed for export by the South-Eastern factories was considerably less than during the month of November, but in order to clear the stocks, it will be necessary to continue exporting to a limited extent for some weeks to come. The London market for cheese is very weak. At the present time colored is realising from 42s. to 43s. per cwt. and white from 45s. to 46s. Owing to the weakness of the London market it was necessary to reduce values a further ½d. during the month. New makes, large and mediums, 5½d. to 6½d.; loaf, 6½d. to 6½d.; semi matured and matured, 9d. to 9½d. per pound

BACON.—The sale of bacon during the month was very satisfactory, and there was a particularly good demand for hams for the Christmas trade. Best local sides, 9½d. to 9½d.; best factory cured middles, 10½d. to 11d.; large, 9d.; rolls, 8d. to 8½d.; hams, 1s. to 1s. 0½d. per pound; cooked 1s. 2d. to 1s. 2½d. per pound.

LARD.—Sold steadily at quotations. Bulk lard, 5d. per pound; prints, 6d. per pound.

ALMONDS.—There was a particularly good demand for both shell and kernels during the early part of the month when traders were buying their requirements for the Christmas trade. In addition to the local sales, substantial quantities were shipped interstate. Buyers now having obtained their full requirements, the market is quiet and only limited business is being done. Softshells and Brandis, 8d. to 8½d.; Hardshells, 4½d. to 5d.; kernels, 1s. 11d. to 1s. 11½d. per pound.

HONEY.—Interstate buyers are only operating to a limited extent and the local market is dull. Although supplies of the new season's "take" are plentiful, the market is steady. Prime clear extracted in liquid condition, 3d. to 3½d. per pound; lower grades, 1d. to 2d. per pound.

BEE SWAX.—All supplies coming to hand are being readily cleared for manufacturing purposes and values are unchanged. 1s. 0½d. to 1s. 1d. per pound, according to sample.

LIVE POULTRY.—As is customary during the month of December, large quantities of poultry reached our market, and during the fortnight prior to Christmas daily auction sales were held. Very strong demand continued throughout the month, especially for quality lots, and high prices were realised. All poulterers report having experienced a very strong demand for poultry and that the Christmas demand cleared the whole of their stocks. Good prices therefore will continue to be obtained, and we advise consigning. Our sales are held every Tuesday, Thursday, and Friday, and crates will be loaned free of charge on application. Prime roosters, 4s. to 5s.; nice conditioned cockerels, 3s. 5d. to 3s. 10d.; fair conditioned cockerels, 2s. 10d. to 3s. 4d.; chickens lower; heavy-weight hens, 2s. 2d. to 3s.; medium hens, 1s. 6d. to 2s. 1d.; light hens, 1s. to 1s. 5d.; couple of pens of weedy sorts, lower; geese, 4s. to 5s. 9d.; goslings, 2s. 8d. to 3s.; prime young Muscovy drakes, 4s. 9d. to 5s. 6d.; young Muscovy ducks, 3s. to 4s.; ordinary ducks, 1s. 6d. to 2s. 9d.; ducklings, lower; turkeys, good to prime condition, 11d. to 1s. 3d. per pound live weight; turkeys, fair condition, 8d. to 10d. per pound live weight; turkeys, poor and crooked breasted, lower; pigeons, 3½d. each.

POTATOES.—New season's, 7s. 6d. per cwt.

ONIONS.—New season's white, 4s. per cwt.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

UPPER NORTH DISTRICT. (PETERBOROUGH AND NORTHWARD.)

WARCOWIE (Average annual rainfall, 11.42in.).

October 31st.—Attendance, 20.

COWS AS A SIDE-LINE.—Mr. R. Pampa contributed the following paper:—"In times of depression the farmer has to consider other ways of making a living besides wheat-growing and sheep-raising. One of the best ways is to run a few good cows, which should help to pay the store bill. I favor the Shorthorn for farmers. The cows are good milkers; the young cattle develop more quickly than most breeds, and realise better prices. The sire plays an important part in production. New blood should be introduced into the herd every few years, because as a rule there is too much in-breeding practised in most districts. There should be a change of bull every three or four years if farmers are to maintain a good class of cattle. This could be done by several farmers co-operating and purchasing a suitable bull. This would be cheaper for all concerned, and farmers would always have a good class of heifers as well. By these methods the class of cattle would always be improving, even if the foundation of the herd were not pure-bred."

FARM HINTS.—Mr. A. Crossman (Hon. Secretary) read the following paper:—"To make a cheap sandpaper spread hot glue over thick wrapping paper; then sprinkle with sharp selected sand. To keep eggs fresh a long while, dip them in melted fat before storing. Worn-out car tyres or machinery belting of rubber and fibre composition can be used to make hobble straps. Saw them into strips with a handsaw under water. Weather will never shrink or harden them, and they are always easy to undo. They will not chafe horses' fetlocks, and will last longer than leather. When grinding tools turn the stone towards the blade; if turned the other way it drags on the edge. Narrow blades such as chisels, &c., should be ground more on the edge of the stone. If held in the centre the face of the stone soon wears hollow, and is spoilt for grinding wide blades. Where grass seeds have been troublesome it will pay fat lamb breeders to shear the belly wool off all the rams. This can be done when the ewes go to the shed for crutching. The cost will be covered by the sale of the crutchings. Kerosene or castor oil is a soothing remedy for the eyes after grass seeds have been removed. When setting out trees for the nursery in land with a clay subsoil, do not dig out basins in the clay. In wet seasons these become waterlogged, and the roots rot. See that any holes made in clayey country have drainage. Fill the hole with decayed grass and leaves. Fruit trees will not do well if their "feet" are in a mudhole. Never hang gates on the posts of a fence; they will either lift or fall. If a couple of stout posts are sunk alongside, and the gates hung thereon, they will last twice as long as if attached to the fence. If obliged to strain to a splitty strainer, have two ends on the wire to be strained, and bring them both through the hole in the strainer. Attach the straining fork to one of these, and strain the wire. Then, without driving the plug, take the loose end and tie around the post in the usual way. The end used for straining can be tied round the other side."

WILMINGTON (Average annual rainfall, 17.43in.).

August 8th.—Attendance, 12.

STATION BRED HORSES FOR FARM WORK.—Mr. J. Moroney read the following paper:—"It is not economical to breed horses for farm work on small holdings in the upper northern wheat-growing districts if a suitable type can be purchased at a reasonable figure from far northern stations. It takes practically 3½ years from the time service of the horse is paid for until the colt is fit to work. For the first few weeks of the foal's life (which is generally fallowing time) the mother has to be spelled, then if the team is not of sufficient strength, some of the work is left undone. Owing to the frequency with which drought conditions prevail, it is not uncommon to have to hand-feed the colt for long periods, and at times the fodder is very costly. If a few cows are run on the pasture required for the growing colt, the profit from the former go a long way towards paying for the full-grown station horse, with which there would be no foaling risk or injury during its growing period." Mr. J. Modystach, in support, said a northern horse was just as easy to break in as a farm-bred horse. The station horse—medium draught—would stand as much work as any other horse. (Secretary, C. Cole.)

MIDDLE-NORTH DISTRICT.**(PETERBOROUGH TO FARRELL'S FLAT.)**

BEETALOO VALLEY (Average annual rainfall, 23.50in.).

September 4th.—Attendance, 11.

HORSES VERSUS TRACTOR.—Mr. P. Curtin read the following paper:—"In making a comparison of these two methods of working a farm of 600 acres over a period of 10 years, in that time there would be seasons when one and then the other method would be more payable. To work a farm of this area the following plant would be required:—12 horses at £25, £300; harness, chains, &c., £4 per horse, £48; total, £348. At the present time a good tractor can be purchased for that amount. Working expenses with the tractor during the year would be:—Ploughing once, harrowing and cultivating three times, including combining:—For kerosene ploughing, 300 acres at 2s., £30; cultivation, 900 acres at 1s., £45; harrowing 900 acres at 6d., £22 10s.; harvesting 300 acres at 1s. 3d., £17 10s.; petrol and grease, £10; oil, £15; depreciation and repairs, £100; total, £240. The cost of working horses can be set down as:—80 tons hay at £2 10s., £200; chaff-cutting same, £10; depreciation on horses, £25; harness repairs, £10; total, £245. To this must be added depreciation on stables, engine and cutter, chaff-house, &c., and also insurance. To start farming on an unimproved farm the tractor at the present time is cheaper than horses." (Secretary, B. Giddings.)

BLYTH (Average annual rainfall, 16.77in.).

October 27th.—Attendance, 16.

THE HORSE, PAST AND PRESENT.—Mr. A. Webber read the following paper:—"The draught horses that are being bred to-day are inferior to those of a quarter of a century ago. The horse of a few years ago was a big, upstanding, big-boned gelding that would work all day, make no fuss about pulling big loads and was never sick or sorry; the big roomy mare that could do her work, carry a foal, and deliver it without trouble; the magnificent stallions and the wonderful horses that used to shunt railway trucks at sidings or on the wharfs. Can anyone say the present-day horse is the equal of those referred to? Which horse does a buyer—be he a farmer or a dealer who comes on to a farm—look for? the big horse. Again, which horse do you point out with pride to a visitor? the big gelding or the big mare, not the light-boned, big-footed horse that is typical of the horses of to-day. The only point to which exception could be taken to the old type of horse was that they had too much hair on the legs. There were not many horses that could be condemned for that, and they could have been plucked, as was done with the new type. Previously, girth and cannon bone measurements were taken, and the bigger the measurement the more proud was the owner. *The New Type of Clydesdale—The Big Footed, Big Bodied, Light Legged Horses.*—The greatest praise the old type receives comes from the very people who are advocating the breeding of the light type, when they advocate two classes at shows; one for the draught and another for the Clydesdale. Will anyone say that the man who takes a size 12 boot has a more perfect foot than the man who takes a size 6 boot? The same applies to a horse's foot; it has no need to be big to be perfect. The big foot is a fault, especially on fallow ground. The long pastern that allows a horse's fetlock to touch the ground is a weakness. No wonder it is said "those horses push a load not pull it." *The small Cannon Bone:* A big man with spindle legs cannot be said to be well built. The legs have to do the work and carry the weight of the body, and a big topped horse with a very small cannon bone and a long and small pastern bone cannot be expected to stand up to his work or last as long as the horse with the big bones. Even the men with the new type horses agree that they cannot get the bone, and use the small boned stallion on big mares to try and bolster up the breed. They will soon have to get back to the big boned stallion, and with small boned mares put to a big boned stallion no end of foaling trouble will result. If you have a big boned, roomy mare, put her to the big stallion and produce a big boned roomy filly that can be safely bred from when this new fashion passes out and the true draught comes into his own again." (Secretary, R. Eime.)

MURRAYTOWN.

September 30th.—Attendance, 17.

The meeting took the form of a debate on the subject “Bags *versus* Bulk Handling of Wheat in South Australia.” The leader of the argument in favor of the bulk system, Mr. N. Scholz, was supported by Messrs. Pitman and Borgas. The debaters in favor of the bag system were Messrs. D. Bleischke, W. Joppich, and O. Reichstein. At the conclusion of a very spirited debate the judge gave a decision in favor of the old system 85 points, bulk handling 82 points. The Hon. Secretary also gave a report of the Annual Congress. (Secretary, E. Pitman.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

BROWNLOW.

August 2nd.—Attendance, 13.

FODDER CONSERVATION.—Mr. R. Steinborner contributed the following paper:—“Conservation of fodder is a farm essential which applies to every farmer that owns stock. Of the many fodders conserved the most important is hay. Care must be taken that this is not carted in too early after it has been cut, otherwise it will deteriorate. Sheaved hay should be left to dry for about three weeks; loose hay about one week. Stacks should be made with a good bed of straw. When building a stack keep the middle higher than the sides to prevent water running into the stack. After the stack is completed a good covering of straw is necessary to keep out the rain. This must be kept down with netting and weights hung on the sides. The only way to prevent mice from getting into a stack is to make it mice proof. Cocky chaff is also a valuable fodder in this district. A good bed of straw is also necessary for chaff heaps. Straw can be made into good fodder, and will keep for years, especially in times of drought. In the discussion that followed Mr. N. Brook said cocky chaff was better fodder than straw chaff as the twine was bad for horses. Mr. H. Roocke said mouldy hay should not be used for horses. (Secretary, F. Roocke.)

FRAYVILLE.

September 28th.—Attendance, 12.

BULK HANDLING.—Mr. H. Ramm read the following paper:—“Bulk handling has been adopted in New South Wales. This State is suitably adapted for the successful working of this system, as it has only one outlet port for exporting wheat. All this wheat flows into this one port or terminal, and is shipped overseas. Farmers have expressed entire satisfaction with this system, claiming that expenses have been considerably reduced, while others express dissatisfaction. Western Australia has also tried this scheme with the same results. Victoria has not yet adopted this system, but recently the Victorian Government decided on a bulk handling system for wheat-growing districts. South Australia has not yet definitely decided whether it should adopt this system, but it is a much discussed and debated question to-day. Geographically South Australia is not suitable for bulk handling. It has a greater number of overseas wheat shipping ports than are used by all the other wheatgrowing States of Australia put together. Wheat steamers are loaded at the wharveside of seven major ports in addition to 45 smaller places dotted along the South Australian coast. These are natural outlets for wheat exported from this State. The huge cost for the installation of terminals at these ports would be prohibitive when one considers that a scheme outlined by the Government embracing two of the major ports will cost approximately £720,000. Two zones will be formed—Wallaroo and Port Adelaide zones. Stations which are connected to these ports and have an average export of 30,000bush. will have elevators and silos erected. Silos are constructed of concrete or galvanized iron—the latter system being the cheaper. Railway trucks have to be made to haul the wheat from the stations to the ports. One of the primary considerations

ROSEWORTHY AGRICULTURAL COLLEGE

THE PRINCIPAL,

Agricultural College,

ROSEWORTHY.

is that of cost to the wheatgrower. Would bulk handling be cheaper than the present system? Corn sacks are a great expense that the wheatgrower has to face at harvest time, and thousands of pounds go out of Australia for these necessities, but the money is kept in the Empire, but by bulk handling there will be an enormous saving to the wheatgrower. Wheat is carted in secondhand bags or specially constructed vehicles. The bags are either tied up or fastened with a skewer, thus doing away with the sewing and ramming bags. The wheat can be transported from paddock to silo without further treatment. Time is also saved at the silo, where the load is weighed on a weighbridge, and with the assistance of another man in charge of the elevator the grain is dumped into a shoot of the silo. The vehicle is then re-weighed, and a certificate issued to the seller on which is given the number of bushels. This certificate is transferable. This would be a much better way of storing wheat than that in vogue at the present time. It would be as good as free wheat, and could be sold to any miller or merchant at full market rates. The wheat at the silo.—In this case the only saving to the producer would be cornsacks and labor. In considering freight rate charges it is obvious that freight must be cheaper than that of bagged wheat. Who will benefit by the cheaper freight, the producer or buyer? The latter because when the wheat is sold at the silo the farmer ceases to be the owner of such wheat. The wheat is transported to the seaport in railway trucks, and then elevated into ships. Here again saving is effected, because grain ships cart wheat in bulk from 2s. 6d. to 3s. 6d. per ton cheaper than bagged. Will bulk wheat bring the same prices as bagged wheat? The containers are worth something to the purchaser. In Sydney at a certain date the estimated f.o.b. price for bagged wheat was 3s. 5½d., representing an approximate return to the growers of 2s. 8½d. Bulk wheat scrip on the same day was 3s. 5½d., with a return to the grower of 2s. 9½d., giving an advantage for bulk wheat over bagged wheat of 1d. per bushel. Does this penny saving warrant the erection of silos? The Farmers' Union has outlined a trial scheme for handling pooled and bought wheat in bulk, and has undertaken to pay all costs in connection with the scheme. Last year they made a trial shipment, and although they had to cut open the bags and tip them into the hold of the ship they loaded nearly 2,000 tons a day, the loading charter being 1,000 tons. The wheat was then sold at 3/16ths of a penny less than that of bagged wheat. If bulk handling comes to South Australia there will be a huge army of men thrown on the labor market. Lumpers would be done away with, wharf laborers and office clerks would be thrown out of work, and at Wallaroo 1,500 men would be thrown on the dole. Cornsacks are made within the British Empire in India. As the unemployment problem is a national one the increase in the unemployed must be considered. Jute farmers would go bankrupt and companies insolvent. India imports some of our wheat, and if we do not buy cornsacks India will look to other sources for her wheat. Bagged wheat will always have a demand, because certain countries are better suited to it. If all the other States adopt bulk handling and South Australia does not, cornsacks will be cheaper, and the price of bagged wheat in excess of that for bulk. If bulk handling is economically justifiable private enterprise would have invaded it long ago. Wherever there is a certain profit the enterprising business man is fairly certain to appear, but so far he has been content to leave this system alone. The present bulk handling scheme may be a good one, but if any scheme is to originate in South Australia let it be controlled by private enterprise." (Secretary, V. Eichler.)

GREENOCK (Average annual rainfall, 21.56in.).

October 9th.—Attendance, 35.

MONEY AND CREDIT.—Mr. E. B. Heysen read the following paper:—"In olden times goods were obtained by a system of barter or exchange, but this system did not always prove satisfactory, and to overcome many difficulties that arose various coins or tokens were evolved. In civilised countries they are usually manufactured from copper, silver, and gold, because these basic metals have a reasonably consistent value. For many years these tokens were the only means of purchasing anything. With the advent of banking institutions a system of credit was begun, when treasury bonds and bank notes were brought into use. At first these bank notes were made only for large amounts for the convenience of customers who wished to transport easily large amounts of money. However, successive Governments gradually increased their use and decreased their value until to-day we have notes of low face value and still lower cash value. At present there is an idea that credit of all descriptions can be obtained to an unlimited extent, but this is erroneous. A bank cannot create credit in the sense of bringing it into existence out of nothing; it cannot lend nearly so much as it can borrow. To quote from 'Banking' by an English authority, Dr. Walter Seaf, 'The banker's business is founded on his deposits, and limited by them.' Messrs. Mills and

Benham, in their book 'Banking and Foreign Exchange,' emphasise that there is one feat that a bank does not and cannot perform—it cannot lend more purchasing power than it receives. H. T. Easton, the author of another volume on credit, says, 'A banker cannot use more than 60 per cent. of his capital and deposits in making loans or discounting bills.' Still the idea exists that the banks can create unlimited credit, that somewhere, locked away in the strongest safe of a bank is some mysterious power which can supply credit without end. Another important limit to the lending capacity of a bank is the necessity for keeping a certain ratio between advances and cash reserves. In Australia the practice is to keep a cash reserve of about 15 per cent. of the total deposits, and this, together with the general trading conditions of the country, fixes a fairly rigid limit to a bank's capacity to lend safely. When lending, it must be borne in mind that the amount of credit is definitely limited to the value of a security the value of which is strictly based on what that security would bring as a result of a forced sale in depression periods. The following is an example. A property is for sale, this property is naturally of greatest value to the owner of the adjacent block, who, to enlarge his own property, will offer more for it than a man further away. This larger price immediately enhances the value of neighboring properties, but does *not* reflect the true value of the land. The purchaser then attempts to raise money on the newly acquired land, but finds that in the banker's mind the value is considerably less than that which he gave for it. The banker knows the purchase price as the "sentimental value" and cannot use that as a basis for a loan. Another point which tends to perplex a man is that when he places money in the bank he obtains only 3½ per cent., whereas, when he borrows it he has to pay 5½ per cent. on his overdraft. This extra 2 per cent. is used by the bank to pay expenses such as salaries, &c., and to cover any losses that might accrue. The bank is only a depot, as is a store, and is entitled to its just profits. It might be interesting to note that 2 years ago the rates were 5½ per cent. for fixed deposits and 7½ per cent. for overdrafts. The Commonwealth was, at that time paying 6 to 6½ per cent. for its Treasury bonds and loans, whereas since the compulsory conversion of all bonds it pays approximately 4 per cent. Why does the Commonwealth pay ½ per cent. more than trading banks? It is well known that the more desperately one needs money the larger the interest rate that has to be paid. The Commonwealth Government, therefore, tried to make its proposition more attractive by offering a larger rate of interest in order to encourage the investor to assist them.

CHANNELS THROUGH WHICH CREDIT CAN BE OBTAINED.

Money is required for expansion, renewal of plant, or some other purpose. The bank manager is approached and the matter discussed. He will want to know what security is offered and, on the value of that, will decide the amount of overdraft. This overdraft is rarely for any stipulated period and the borrower can at any time be called upon to reduce it. However, it is not intended to convey the idea that if working on an overdraft a forced sale may be held at any time. So long as interest is met and reasonable use of the money is made the banker knows that it is to his interest to allow matters to stand. He, however, likes the borrower to meet him occasionally and discuss his position. The overdraft is really the best form of obtaining credit, for each time a transaction takes place the interest is calculated so that one only pays for the money on loan. In other forms of loans, however, certain interest dates are fixed, and even if reduction is made before the due date, the full amount of interest must be paid.

MORTGAGES.

Another mode of obtaining money is by means of a mortgage. Here, too, a security must be given, but the difference between this and an overdraft is that payment cannot be demanded until the date on which it is due. Bank mortgages, however, like overdrafts, are payable in demand. In the event of a mortgage not being paid when it falls due, a forced sale can be made. Once it falls due, unless it is renewed, the mortgagee can cause the sale to take place at any time he wishes. For safeguard, therefore, it is wise to make application for renewal before the time expires. A mortgage will be accepted as security by a bank for overdraft. The law regarding second mortgages is interesting. A second mortgagee, may, when the first mortgage falls due, compel the first mortgagee to foreclose and accept the amount due to him. When foreclosure is made, the security must be sold by auction and the balance, after the creditors have been paid, is paid to the unfortunate who has been sold up.

BILL OF SALE.

Another form of security is the bill of sale. Here the articles are nominally sold to the lender, and unless the amount borrowed is repaid, become his absolute property, the borrower having no more interest in them. As with mortgages, a bill of sale should be registered in the interests of both parties. A bill of sale is usually given

on some moveable property such as stock, implements, and furniture. A man wishes to borrow money. He has a harvester and as it is winter time does not need it for some time. He therefore goes to someone with money to lend and signs a document which states that his harvester has been sold for a certain sum of money. This document is held by the lender while the borrower keeps the machine until such time as the borrowed money and interest is repaid. If this is not done, the lender has full legal rights to take possession of the machine and to regard it as his own. Should the borrower at any time prior to repaying the lender attempt to dispose of the harvester, he can be charged and convicted of larceny.

HIRE-PURCHASE.

The hire-purchase system appears at first glance an admirable method of obtaining goods on credit. By this means practically anything can be obtained, but the system has its drawbacks. The article does not become ones property until the final payment is made. The purchaser contracts to hire the car for a stipulated sum at certain periods. Should he fall in arrears with these payments the seller can take possession of the car. The matter, however, does not end there. The hirer can be sued for all arrears of payments besides losing all interest in the car. Should he be able to make up arrears, once the car is repossessed, he still has no claim on the car, for those arrears constitute a breaking of the agreement, losing for him all his rights. Here again a chat with the seller of the car will often prove advantageous, and an extension of time obtained which, if put in writing, safeguards the buyer.

PROMISSORY NOTES.

The worst form of security however is the promissory note. Here the borrower pledges himself. By means of a document, very often in the form of a post-dated cheque, he contracts on a certain date to pay the specified amount. Should this not be met, the creditor, by means of the court, can obtain an order to sell sufficient of the debtor's goods and chattels to cover the amount payable.

According to the law there is no obligation whatever for a lender to ask for either his principal or interest when it falls due. The onus is on the borrower, who cannot claim that he had no notification, and unless he pays the lender can claim a breach of contract." (Secretary, A. Schubert.)

November 6th.

WINE MAKING FOR THE GROWER.—In the course of an address on this subject Mr. C. Pollitt, of Tanunda, dealt almost entirely with the sherry type of wine, saying that sherry was almost the only wine that a grower could manufacture successfully without having an elaborate plant, and it could be successfully stored for maturing in any shed. He maintained that a high class sherry could only be made in small quantities, and for that reason a grower would have a decided advantage over the big wine maker. The grower could more readily give the small attentions necessary for manufacturing a really high class sherry type wine than a wholesale manufacturer, and there was always a keen demand for a high class sherry. Mr. Pollitt said suitable varieties for making sherry were Riesling, Pali Mena Blanco, Sherry, and Pedro. Wine for making sherry should not be fermented on skins, but made into vinegar or spirits. On being asked whether Tokay and Madeira made a good sherry Mr. Pollitt replied that those grapes make a good Tokay and Madeira type. Here again the small maker could produce a much better class of wine than the big wine maker, because those wines also required little attentions that the larger maker could not give. Mr. Pollitt insisted that all grapes should be allowed to develop a big Baumé on the vines, or the grapes picked and allowed to lie and dry from a day to a week; grapes treated in that manner for wine would not require so much spirits and would produce a better type of wine. Frontignac made a good wine and was drinkable at the age of 12 months, but it did not sell so readily as Sherry or Tokay. White Hermitage, said Mr. Pollitt, was a very hard wine to handle, and was considered of very little value in the Greenock district. It was possible to make sherry from Doradillo grapes, but it was a low class wine, with a Doradillo flavor and required a large quantity of spirits, which made it an expensive wine to manufacture. The very best was only second class wine, sometimes it was used for blending, but the speaker strongly recommended that this should not be done because it was far better to have a small quantity of good sherry than to have a larger quantity of second class wine. On being asked why Grenache had evidently gone out of favor with wine makers in the district, Mr. Pollitt replied that he could not say, it was possible to handle large quantities very successfully and make wonderful ports from this grape, but it did not last much longer than 5 years. It did not make the same class of wine as Shiraz. One member asked what would happen if 50 per cent. of the growers processed their own grapes, the reply was that the big wine

makers would become their best customers once they became used to that, and they probably would find that they could buy better wine and cheaper wine that way than they could produce themselves. An intelligent small wine maker, using common sense could always produce a higher and better type of wine than the wholesale manufacturers. White and Red Malaga made fine wines. The White Malaga especially made a very pleasant and full bodied wine which had a very good sale. Red Malaga made a good pale port. Would it be possible to make a good unfermented wine, suitable for non-alcohol drinkers, which would be tasty and attract the taste of the public? Mr. Pollitt's reply to this question was that as yet the manufacture of unfermented wines was not a success, they had a poor flavor and no keeping qualities and often it was found that they became an intoxicating drink after some time. The Pure Foods Act only allowed sulphate compounds in manufacturing unfermented wines, and those compounds did not appear to be a success. (Secretary, A. Schubert.)

BOWEL DISORDERS OF HORSES.—Mr. J. Baum read the following paper:—*Stoppage of the Bowels.*—This is a common condition among hard working and well fed horses. Usually is it not a fatal disease if the proper treatment for it is undertaken without delay. *Causes:* Improper feeding, irregular work, bad food, bad teeth, and insufficient water. *Symptoms:* Dullness, loss of appetite, and a disposition to lie down. Even while the other animals are at their midday meal the affected one will sometimes be found lying in his stall. As time goes on there is a slight increase of pain indicated by the animal pawing and looking around to his flank. He now lies more than he did at first, and is often found lying flat on his side with his head on the ground. He may lie in this position for half an hour at a time, then he may get up, walk a little, and lie down again. When on his feet he sometimes strains as if trying to pass water, but without relief. He does this so often that the owner is led to think that the horse is suffering from a spasm at the neck of the bladder or some kidney disease, and as a rule treats him accordingly. The cause of straining is due to pressure on the bladder by an overloaded loop of bowel. There is usually little pain and no fever at the outset. *Treatment:* Give at once linseed oil 1 pint, turpentine $\frac{1}{2}$ oz. Follow this with the following as soon as it can be made ready:—Powdered aloes 1 oz., linseed meal 1 oz., belladonna extract 1 dram. Mix the whole in 1 pint of boiling water, stir together, and give dose when cool enough. If the stoppage is due to large quantities of dry food it may be 48 hours before the medicine operates, and then it is not likely to cause scouring. It will be observed that the horse will begin to eat a little many hours before the medicine acts. While waiting give an occasional injection of warm water and soap. Do not be tempted to give pain-killing medicine unless the animal is in pain. About 80 per cent. of those cases which are thought to be water troubles are bowel troubles, and should be treated as such.

INFLAMMATION OF THE BOWELS.

This is a very serious condition, and one that will prove fatal unless promptly and skilfully handled. *Causes:* Irritant food, chills, drinking frosty water, eating frosty grass, exposure to inclement weather, fording streams in cold water when the animal is in a heated condition, and the giving of too violent purgative or irritant medicines.

Symptoms: When first seen to be ill the animal shows more or less distinct signs of pain. He lies and rises just as when affected with gripes; hence most farmers mistakenly treat such cases as gripes or colic and give only a soothing or pain-killing drench. In doing so they run a great risk of losing their horses. At first small quantities of dung are passed, and the owner is likely to reason from this that the bowels are all right and the water must be the trouble. These first pellets of dung are of a brownish color, later pellets are smeared or streaked with blood. After this no more dung is passed, but if an odd pellet is found in the rectum it is likely to be coated with a mucous lining. The pulse is increased in rapidity, and may go up as high as 100 per minute, but it runs about 80 on an average. In some cases the horse has a habit of turning up his upper lip, but too much reliance should not be placed on this as a symptom of this disease. The chief indications of inflammation of the bowels are constant pain with no intervals of ease as in colic or gripes, rapid pulse, blood-stained dung, and the fact that gripe drenches have little effect in easing the pain or of slowing the pulse. *Treatment:* Give at the outset linseed oil 1 pint, follow as soon as possible with Barbados aloes 4 drams, linseed meal 1 oz., belladonna extract 2 drams. Melt and mix the whole in 1 pint of boiling water, and when cool give as a drench. If the animal is indoors, or if he can be protected from cold winds, wring a blanket out of boiling water, making it as dry as possible, place it around the belly, and cover over with a dry horse rug. Change the blanket every hour or two, and take great care

that the horse is not chilled when changing it. If pain becomes excessive during the above treatment try to control it with a dram of belladonna extract every two hours, or give the following drench every two or three hours:—Laudanum 1oz., sweet spirits of nitre 1oz., linseed oil 4ozs. This is all that a farmer should do in a case of this kind, and in many cases it is quite sufficient, but whenever possible the services of a veterinarian should be obtained, because treatment should be modified to suit changes that take place during the progress of the disease.

COLIC OR GRIPES.

This is probably the disease best known to the horse owner. It is of very frequent occurrence, and almost every farmer is familiar with the symptoms which accompany it. It consists of spasm or cramp of one or many portions of the bowel. *Causes:* Feeding at irregular intervals, allowing horses to bolt their food, irritants in the bowels such as worms, and indigestible food, bulky food, frosty water, sudden changes of temperature, and over driving. *Symptoms:* Pawing and scraping with the fore feet, looking around to the flank, attempting to lie down, lying and rising, rolling, sweating, groaning, and then an interval of ease. During attacks of the spasms the pulse beats are increased in number, going as high as 70 or 80 per minute, but when relief comes it gradually falls back to normal. When soothing or pain-killing doses are given the symptoms become greatly modified. *Treatment:* Give the following as a drench:—Powdered aloes, 1oz.; treacle, syrup, or sugar, 2 tablespoons; linseed meal, 1oz.; boiling water, 1 pint. Mix, and when cool add laudanum, 2ozs.; sweet spirits of nitre, 2ozs. If aloes are not at hand use 1 pint of raw linseed oil instead. The linseed meal is used to prevent the aloes from knotting when the water is added, and it may be dispensed with when linseed oil is used instead of aloes. If pain returns some time after the above dose has been given repeat the laudanum and sweet spirits of nitre in the same quantities in a small quantity of linseed oil. If thought necessary give an injection, and apply hot blankets to the belly.

FLATULENT COLIC.

This is a condition very different from spasmodic colic, and is much more difficult to treat. It is due to fermentation of food or other matter in the bowels. *Causes:* Eating green food, frozen grass, and wet sheaves in harvest time. *Symptoms:* The animal shows all the signs of spasmodic colic, but in addition becomes greatly distended at the flanks as the disease progresses. If this bulging at the flanks is detected, and it is known that the animal has been subjected to any of the causes mentioned above, then treatment for this condition should be adopted from the start. If the distension is not observed, and the case is mistaken for one of ordinary gripes, then no harm will result if the gripes treatment is continued, because nothing seems to be of much avail in dispelling gas, although many substances are recommended for that purpose. It will generally be found that until the aloes operate no relief will be obtained. As there is aloes in the gripe dose recommended, it will be found a safe method of procedure to give that dose in doubtful cases rather than do nothing at all. *Treatment.*—Give the following as a drench:—Powdered aloes, 1oz.; linseed meal, 1oz.; hyposulphite of soda, 2ozs.; treacle, syrup, or sugar, 2 tablespoons; boiling water, 1 pint. Mix the whole together, and give when cool. If relief is not obtained continue giving every three hours:—Turpentine, ½oz.; hyposulphite of soda, 1oz.; linseed oil, 6ozs. In this disease it will be found that when all the doses known to the farmer have been given and the animal is still in pain no time should be lost in securing the assistance of a competent practitioner. (Secretary, O. Verrall.)

October 30th.—Attendance, 31.

HAYMAKING.—Paper read by Mr. A. Nitschke:—"Select a piece of ground, as free from stumps, sticks, and stones as possible, to be sure of getting the maximum cut. In many instances the crop is cut too soon, and the hay is not as good as would be the case if it had been left until the grain is full and has lost its green colour. *Stooking.*—Stooks should be of an average number of sheaves—from 20 to 25—so that the hay dries evenly. Stooking may be done directly after the binder, or the sheaves may be left to dry for a day or so. When stooking, the first sheaves should be put upright with not too much lean given the outside sheaves because if for any reason the hay is left out in the field for some time, the stooks will not go flat, and in case of heavy rain, very little damage will be caused. *Stacking.*—There are several methods of stacking, the one mostly in use being the butt out method. I favor the following method:—First, the outside layer is always laid butts out, sheaves should not be placed on the flat, but at a slight angle with the knot down. The second layer with heads out to cover the string of the first layer. Then place the next layer with the butt against the butt of the second layer, and repeat until the centre sheaves of the stack meet

the butts on heads, &c., next or third layer from outside, heads out again and follow the same procedure, gradually getting the centre of stack about 3ft. higher than the outside. With this method there will be less damage by rats or mice, and more hay can be stacked in the same space. Vermin can only get along where the butts of sheaves meet, and to get to the grain the mice must eat their way right through the sheaves. Stacks can be built with round or square ends or corners, and if straw is not available to put on the stack when it is finished—and knowing this beforehand, a stack can be made to withstand a lot of rain without any straw covering by adopting the following method:—The sheaves for the eaves may be placed out about 6in. over the walls of the stack, and all following layers gradually brought back and tapped level with a board on the end of a stick; the end of a petrol case makes a nice handy size, nailed on to a piece of light timber. The sheaves are tapped back to make the roof of the stack level with an angle of about 75° and if no straw is put on, the stack will stand any amount of rain, none of which will penetrate to the sheaves." (Secretary, C. Verrall.)

LONE PINE.

A BACHELOR'S LIFE ON A MIXED FARM.—In the course of a paper on this subject Mr. A. B. Fromm said that in mixed farming the jobs that had to be done kept one busy from early morning until late at night, and perhaps only those striving as bachelors for a living on a small holding were in a position to appreciate the situation. One never was able to say, "To-morrow I have nothing to do," especially with 25 acres of garden, five cows, 150 to 160 sheep, two horses, pigs, and 300 to 400 white Leghorn fowls. First thing in the morning one found the cook and the fire both out, and if the need of a cup of hot coffee was felt the only answer was, "Do it yourself"—the theme of the whole day's work. After deducting 25 acres of garden, approximately 80 acres was left for grazing or cropping. He preferred the former, for the more paddocks one had the more stock could be kept. Sheep and fat lamb raising were perhaps the most profitable, especially this year with increased prices for wool and lambs by comparison with the last few years. They also required less attention than cows kept for cream and butter. With cows there was day in-day-out milking, separat-

ing, and cleaning up. With, say, five cows, quite a few hours were required every morning and night, and another disadvantage was that one was tied down to the place. Although almost as big a tie, he preferred fowls, because while they required attention they were always handy if kept properly housed and supplied with an automatic system. They also showed slightly more profit than cows, but must be maintained under modern conditions, none being kept for more than three laying seasons at the very outside. Chickens have each year to be obtained to replace the culled fowls. And gathering, cleaning, grading, and packing eggs for market was another of the bachelor's tiresome jobs. It generally had to be done at night by lamplight, while the wife or children of a married man would have time to do it during the day. Then came the many other jobs that filled in the lonely evenings one after another. Of course the monotony would be relieved if finance permitted the securing of a radio set so that one could listen in. But in the main one heard the same echo and re-echo of the morning, "Do it yourself. (Secretary, S. Turnbull.)

NANTAWARRA (Average annual rainfall, 15in.).

November 2nd.—Attendance, 6.

THE BROOD MARE AND FOAL.—The following paper was read by Mr. L. Belling:—"In order to arouse interest in horse breeding, the farmer should encourage his son to save his money and purchase a mare rather than wait until he is old enough to start farming on his own. Procure the best mare possible, and breed from the best stallion in the district. Start breeding from a mare at three years old. A mare's period of oestrus is about 1 week, with 3 weeks between each period. If a mare proves difficult to get in foal, give her a douche of bicarbonate of soda, at the rate of 3 to 4 table-spoons to 1 gallon of warm water one or two hours before service. The brood mare should never be over-worked but kept in fairly good condition. A mare in foal needs every care to prevent abortion, which may be caused through hard work, jamming through narrow gates, kicks, falls, or serious illness. Any mares that have aborted should be kept separate from other mares for a few days. In case of abortion a mare should always be given a wash-out with weak Condy's fluid. A wide swing should be used when a mare is heavy in foal. If possible, work her on the outside of the team, if more than one, work them side by side, because mares that are in foal seldom bump each other. The mare should be kept in steady work until within a week or fortnight of foaling, and then put in a small paddock, one near the home for preference, where she can be watched and given assistance if necessary. First it is necessary to have a little carbonised string with you in case the navel cord has to be severed. If the head of the foal is not resting on its forefeet it should be turned. When working around a mare, hands should be cleaned and disinfected, a little oil is helpful, too. The work should be done as quietly and quickly as possible. If the mare foals all right, she should be left alone for a while until the foal can find the use of its legs. After it can get about it should suck and then have the use of its bowels. If the afterbirth does not leave the mare in 8 to 10 hours remove it gently by hand. The first mare that foals should not be turned into the same paddock as the other mares until the foal is about a fortnight old. After the first foal, the horses do not take so much notice of the others. To give a foal the best chance the mare should not be worked, keep her in good condition. Foals should be weaned at about 6 months old and kept in a yard or small paddock. They should also be well fed; a little Epsom salts in their feed daily is very good. Handle the foals so that when they are ready to break in this job will not cause very much inconvenience. They should be broken in to work at from 2½ to 3 years old." Mr. N. Robinson spoke on the benefits of breeding good stock. Mr. A. F. Herbert gave examples of good breeding and the care that was necessary with breeding animals. The Hon. Secretary (Mr. S. Herbert) spoke of an experience of two pregnant mares jostling in a team, one mare giving birth to a dead foal. He said a mare could be worked safely to within a day or so of foaling providing the work was constant and regular. Mr. E. Herbert mentioned that foals were weaned at 3 months in cases when fed on bran, &c., but a foal must not be made fat by hand feeding.

SUTHERLANDS (Average annual rainfall, 10.82in.).

September 7th.—Attendance, 19.

SHEEP IN LOW RAINFALL AREAS.—Paper read by Mr. N. Bahnisch:—"For this district I favor the Merino that will grow a medium wool of good quality. In addition, the Merino is more easily controlled than the English or mutton breeds. If a flock is kept for breeding, endeavor to procure the best class of sheep that finances will allow. Large-framed, plain-bodied ewes of good constitution should be kept, using rams of similar type, with soft, clean faces, and wide open horns. Shearing is a good time to class the flock, marking off any sheep that do not conform to the desired type. Quality

of wool, conformation, constitution, hairy breech, and faulty mouth should be kept in mind when classing. It is desirable to dispose of any sheep not required—especially young sheep—before grass seeds become troublesome. If possible, have the ewes lamb when a supply of green feed can be expected. Where paddocks are small, 2 to 2½ per cent. of rams should be ample. Under normal conditions, a ewe comes in season every 3 weeks, so that a joining of 6 weeks means that each ewe is in season at least twice. Ewes should be crutched 3 or 4 weeks prior to lambing, and at the same time the wool removed from around the udder to give the lamb a better chance to find the teat. Crutching and jetting help to minimise fly trouble, but any sheep that are struck should be attended to at once. Gives ewes well watered and well sheltered paddocks in which to lamb. All water supplies must be kept very clean. Sheep on fresh water readily take salt if put in a trough near the watering place. It is valuable to keep sheep healthy when no green feed is available. Maiden ewes, when possible, should be lambed down with the other ewes. The older ewes have a stealying effect on the young ones, who are usually timid and easily frightened when lambing, and will sometimes leave their lambs. Ewes should be gone through as often as possible when lambing, and any having trouble assisted. It is a good practice to sow an area with green feed for the ewes and lambs each year, thus ensuring earlier feed and a good start for the lambs. Tailing can be done when lambs are from 4 to 6 weeks old, providing the weather is not frosty. Before lambing begins, baits should be laid for foxes, and continued throughout the period of lambing. This can be done by dragging a trail and laying baits treated with strychnine; also any lambs that die can be poisoned. Sheep do not require the amount of attention that other sidelines do. They give a double return—wool and lambs. A flock of ewes is the most profitable. Merino lambs are the best for the low rainfall districts, because if unable to fatten the lambs in the lean years they are valuable as wool producers. When a lean season is experienced the surplus sheep can be disposed of, saving only the best ewes, and then the flock can be built up when favorable conditions return. Do not overstock. A few sheep well kept bring in a greater return than a large number underfed. In a late season it pays to hand-feed lambing ewes until green feed comes. Oats and hay chaff is the cheapest and most valuable feed." (Secretary, E. Schiller.)

October 5th.—Attendance, 25.

SOIL CULTIVATION IN THE SUTHERLANDS DISTRICT.—Paper read by Mr. N. Niemz:—"Much is still to be learnt concerning the correct handling of mallee soils. The matter has been further complicated during recent years by the tendency of many of the mallee soils to drift, spoiling much of the cultivation work. Theoretically, it is not correct to leave stubble residues on the surface or to plough them in, neither is it correct to sow ploughed areas lightly and graze them off instead of fallow. Farmers have learned, however, that they cannot economically plough in unrotted straw, because this gives trouble with subsequent cultivation, and also is not completely decayed before the sowing of ensuing crop, causing weakened plants and increased disease infestation. Experiments have proved that cultivation methods have mostly shown that the earlier the fallowing work is done the better will be the result. It would appear, in this district, that time of fallowing has a very important bearing on the resulting crop. During recent years in particular farmers who have completed their seeding comparatively early, and have immediately started fallowing, finish the initial operation before the end of August. It has been experienced that not later than July is the best time for fallowing, if good results are to be expected. Fallowing at any period prior to the end of July gives very similar results, but at any later date there is a definite loss. Summer fallowing has not proved as effective as early winter fallowing, so far as can be noted. Farmers in this district have learnt that it does not pay to work the soil deeply. Seed-bed consolidation is difficult to obtain, owing to mallee soils and low to moderate rainfalls, and it has proved advantageous to leave the subsurface layers undisturbed. There have been many examples of reduced yields where the fallowing has been too deep, and so the majority of successful farmers do not plough to a greater depth than 2ins. to 3ins. When winter rains are normal at fallowing time, there is a considerable growth of grass and weeds in the paddocks. No implement will destroy and bury these so effectively as the mouldboard plough. In dry seasons, with comparatively little growth of pasture, cultivators do quite effective work. The implement for fallowing will thus always be controlled by the seasons, and farmers will need to choose that which—while being the most economical—will destroy weed growth and at the same time stir up all the soil to an even regular depth. In areas liable to drift some farmers are using the tine cultivator for fallowing, the object being to leave the grass and stubble residues on the surface, instead of burying them, with the idea of preventing the displacement of surface soil by wind. This treatment makes cultivating very difficult, but any method which prevents drift is worth trying, and there have

been quite good crops grown on land treated in this manner. There is at present a wide difference of opinion between mallee farmers as to the amount of cultivation necessary on fallows. It is certainly not wise to cultivate this country to a smooth even surface during spring and summer, because wind is almost certain to spoil the work. Because of this, the use of harrows is steadily declining. It seems quite necessary that the surface be left somewhat ridged, across the direction of the prevailing wind, if possible at least until after harvest. The tine cultivator for fallow working declined in popularity for some years, owing to easier cultivation with the spring-tooth combine. It would seem that too much cultivation prior to harvest leads to drift, yet weeds must be controlled. The practice of many successful farmers during the months when winds are likely to cause damage is to control weeds by sheep, as far as possible, and when cultivation is essential, to leave the surface well ridged. Cultivation after a summer rain can always be depended upon to increase the yield, probably due very largely to the activity of nitrifying bacteria in the soil at this time. Farmers should be ready at any time after harvest to take advantage of rain which may fall. Those weeds most commonly seen in wheat crops in this district are wild mustard, iceplants, wild oats, buckbush, soursobs, &c. *Wild Mustard*.—This weed is difficult to control, because of the large amount of seed produced by the plants, and the fact that the seed lives for a long period without germinating if buried deeply in the soil, a characteristic shared by wild oat seed. Wild mustard seed near the surface does not germinate at once, and so farmers are troubled by successive germinations after each autumn rain. Fresh seed may be brought up by general cultivation at too great a depth, or by some tines of the cultivator being strained and so working too deeply. Each fallowing is a partial means of control, so portion of the seed then germinates almost immediately, and care should be taken subsequently that cultivators work to a shallow depth—less than the depth of fallowing—to avoid continually bringing other seed near the surface, where, with air and moisture, it germinates. *Iceplants*.—In a wet season this plant causes much damage to cereals. The plants when established are most tenacious of life, and often continue to grow when almost completely buried, when uprooted and lying on the surface. Under wet spring conditions, in the absence of sunny, frosty, or windy weather, this weed is impossible to kill, and is responsible for destroying quite large areas of crop. There is only one means of effective control and that is to kill the weed in the seedling stage. *Wild Oats*.—The wild oat is chiefly noted for the long period during which the seed will retain life in the subsurface soil without germinating. Even when near the surface, it fails to germinate with the first rains, appearing often after the crop is sown. This is probably due to the hairy coating of the grain, which keeps the soil moisture away from the seed itself for a time. Methods of control are similar to those for wild mustard—early fallowing with later cultivations not disturbing any seed in the subsurface layers. *Buckbush and Biennial*.—These two weeds are very easy to control. The tine cultivator is the best implement to kill these weeds. The biennial grows for a period of two years and then disappears. *Soursobs*.—The only successful method to control soursobs is to cut them with a rigid-tined cultivator every time they appear. Very little can be done towards eradicating the weed during spring and summer. The rigid-tined cultivator fitted with wide shares is the best implement to use to deal with this weed. The cultivation of fallow, particularly on the lighter soils in this district, should be as shallow as is possible with effective destruction of weeds. Good cultivation in this district is responsible for largely increased crop returns." (Secretary, E. Schiller.)

November 2nd.—Attendance, 22.

Mr. E. Boehm delivered an address, "Improvements in the Farming Practices of the District." He dealt with better methods of soil cultivation by working the land as often as possible after rain and to avoid working the land too deeply. In many instances a spring tine cultivator could be used with satisfactory results. Only varieties of wheat such as Gluyas, Nabawa, and Rancee, which were suited to the district, should be grown. Barley should be sown and used as a fodder for livestock. Farmers should also conserve more fodder in the form of chaff and straw in seasons of plenty to be able to face lean years. More attention should be paid to sidelines such as cattle, sheep, and fowls. Farmers should dispose of their present livestock and secure herds of good reputation, and then make use of well-bred sires. Linseed meal should be fed to livestock in poor seasons. One ounce of superphosphate and 10z. of salt would serve as a lick for livestock. Cream should be sold at least once a week and eggs twice a week in summer and once a week in winter to secure best returns. Implements should be kept under cover—sheds covered with straw provided a good protection against rain and sun. Bookkeeping was too often neglected by farmers; books should be kept to know how the business is progressing. (Secretary, E. Schiller.)

TRURO (Average annual rainfall, 19.96in.).

August 21st.—Attendance, 18.

HARVESTING ECONOMIES.—Paper read by Mr. T. Klemm:—"The seeding of the different varieties of wheat should be conducted in such a manner as to obtain an almost even maturing at harvest time. Sow the late kinds early and the early varieties late, so that a quick hay cut will be assured. The hay should be cut while the grain is in the doughy stage and then stooked as soon as possible after the binder, making the stooks not too big to obtain a good curing. Not more than 20 sheaves are needed to make a fair size stook, the oblong stook being the quickest to dry the hay, but requiring more time and skill to make. With good drying weather, the hay should be fit to cart in two weeks. Every effort should be made to get the hay carted before reaping commences. By the time the hay has been carted the wheat will be ready for stripping, but it should never be harvested until thoroughly ripe. All machinery should be overhauled and repairs carried out before harvesting is commenced to avoid delay. I favor reaping with the harvester or header, especially where there is only one man on the farm. The harvester can be worked on nearly every class of land unless very hilly or rough country, where it would be better to use the stripper. By taking care and a personal interest in the harvester, a good sample can be procured, just as much grain gathered as with the stripper, the chaff saved, and many years of good service obtained. With the harvester at the end of the day all the wheat is stripped, cleaned, and in bags ready to be sewn up and carted away. Further, the wheat can be carted off the fields and should a damp morning or a cold day occur the grain can be carted to market, thereby often securing a better price. There is also less risk of having it destroyed by fire. If the crop is taken off with a harvester costs will be: 8ft. harvester £160, chaffsaver (if required), £8, 168. To harvest with a stripper—8ft. stripper £110, winnower £110, engine £33, £253—a balance of £85 in favor of the harvester. In cleaning the wheat additional expenses have to be considered; extra man for cleaning and benzine for the engine plus your extra work. The man with the harvester has the easier work of letting the horses do the reaping and cleaning at the same time. Last harvest some farmers were still cleaning wheat, while others with the same acreage had their wheat carted and their paddocks cleared. Cleaning wheat is the hardest job on the farm. I do not believe in feeding much cocky chaff. A cow cannot give fair returns or a horse work if fed on cocky chaff alone; it has very little feeding value. Feed is the only reward the horse gets for its services, and mixing grain with cocky chaff to make it nutritious and palatable does not pay in normal years in this district. When a good crop of hay can be grown it simply means separating the grain from the chaff in the first place only to add it again at a later time. Yet it is a wise policy to save some cocky chaff and feed it to young cattle during winter or to dry cows and foals by mixing it with some hay chaff. A farmer should always provide an ample supply of hay to carry through in case of drought, because one year's hay buying will deprive him of several years' savings. A good supply of straw should be kept on hand—tied and loose—to chaff with hay if necessary in a drought. Straw, if properly stacked, will keep for years, while cocky chaff gets damp and mouldy. Oaten straw is preferable, because it is of more nutritive value. In prospect of a good harvest, cornsacks should be secured at an early date; the price of them is generally inclined to rise at harvest. To avoid inconvenience in case of a shortage and before using them, they should be spread out in the sun to stretch to get a chance to fill them to their utmost capacity. It is advisable to crush wheat or oats instead of using pollard or bran. Crushed wheat has a far greater feeding value. Although farmers, especially the younger ones, cannot be without long debts, they should endeavor, in most cases, to pay cash for their other purchases. Do without it or try to carry on with old things. If this had been more widely practised, many a farmer in this State would be in a better position." (Secretary, L. Davis.)

BOOR'S PLAINS (Average annual rainfall, 15.61in.).

September 7th.—Attendance, 12.

COMMON AILMENTS OF THE HORSE.—The following paper was presented by Mr. H. Queale:—"Many of the sicknesses that come under the notice of horse owners are due to ignorance, and quite often to negligence. The following gives the pulse, respirations, and temperature of the horse in a state of health—any serious departure from it is indicative of disease:—Pulse beats per minute, 30-48; respirations per minute, up to 15; temperature, 99 degrees. The usual outward signs of sickness are lack of appetite, an indifferent attitude to surroundings, and sometimes signs of pain and distress. *Strangles.*—Usually attacks young horses up to 2 or 3 years of age. It is due to a microbic poison entering the system of susceptible subjects. The symptoms are:—The animal goes off his food, and shows a difficulty in swallowing. The nose is constantly protruded, with yellow mucus discharging therefrom. The coat becomes dry and starchy, the hair appearing to stand on end. As the disease advances a swelling forms under the throat and behind the jawbone. There is considerable fever, indicated by a rapid pulse and increased temperature, and there are occasional fits of shivering. Immediate attention usually obviates any trouble. *Sore Shoulders.*—Caused chiefly by bad-fitting or dirty harness, by working horses in an unfit condition, and by bruises. A loose collar causes friction, resulting in chafing and blistering. A collar that pinches cuts off the blood flow, the skin dies and falls off, exposing the flesh to the surface of the harness. The symptoms are flinching and unwillingness to give a straight and honest pull. Continuous sores also cause a horse to lose condition. *Sidebone.*—This condition consists of calcification of the flexible cartilages, or gristles, which are attached to the upper and posterior part of the coffin bone. It is caused by concussion, treads, and other injuries, and hereditary predisposition. Many believe that shoeing with very high heels is a fruitful cause. Lameness is not always present. When the disease is suspected, lift up the foot, grip the cartilage with the finger and thumb, and if it bends backward and forward, then that cartilage is free, or, at most, the disease has just begun. If the disease is present to any extent the cartilages will feel like bone. In bad, chronic cases the hoof becomes contracted, and is more upright than normal in appearance. It is then spoken of as a boxy hoof. *Ring Bone.*—This consists of a bony growth on the pastern bone, caused by concussion and injuries and hereditary predisposition. Short, upright pasterns predispose to them, and is most common among draught horses used for road work. There is usually lameness, but not always. The enlargement can usually be seen or felt. *Septic Metritis.*—The inflammation of the womb, due to the absorption of bacterial poisons. It is met with most frequently shortly after foaling. It is due to the introduction into the womb of poison producing germs. This is accomplished very frequently through the agency of dirty hands and instruments of those who render assistance at foaling. Retention of the whole or a part of the after-birth is also a common cause. If this is not removed within 12 hours after foaling there is a danger of this disease; if retained for 24 hours trouble is almost certain; while if neglected for 48 hours there is grave danger of the mare dying from septic metritis. Symptoms are great constitutional disturbance, indicated by rapid pulse, high temperature, loss of appetite, and dullness. Breathing is fast; frequently the milk is reduced, and sometimes stopped altogether. A very sure sign is the presence of a brown-colored fluid in the womb. This fluid has a nasty, sickening odor, and is very poisonous. *Inflammation of Kidneys.*—Causes:—Chills, injuries, improper food, bad water, and parasites are among the common causes. Symptoms:—Stiffness, walking with a straddling gait, the hind legs being kept wide apart; the urine is passed in small quantities; is highly colored, and sometimes contains light, yellowish flakes. As the disease advances the urine stops altogether. This is an important symptom—the non-voidance of urine for days. *Inflammation of Bowels.*—A serious condition, which proves fatal unless promptly and skilfully treated; caused by food containing irritant matter, chills, drinking frosty water, exposure to inclement weather, and the giving of too violent purgative or irritant medicines. The chief indications are:—Constant pain, with no intervals of ease, as in colic or gripes; rapid pulse; blood-stained dung; and the fact that gripe drenches have little effect in easing the pain, or of slowing the pulse. Do not confuse this with the previous complaint. *Stoppage of Bowels.*—Common among hard working and well-fed horses, caused by improper feeding, irregular work, bad food, bad teeth, insufficient water, or water that the horse does not like. The symptoms are:—Dullness, loss of appetite, and a disposition to lie down. As time goes on there is a slight increase in pain, indicated by the animal pawing and looking round to his flank. Then he will lie down flat, with head on the ground. He may get

up, walk a little, and lie down again. When on his feet he sometimes strains, as if trying to pass water, but little or none comes. The cause of this straining is due to pressure over the bladder, of an overloaded loop of bowel, and can be felt by exploring in the rectum. *Colic, or Gripes*, is probably the most frequent ailment. It consists of spasm, or cramp of one or many portions of the bowels. Causes:—Feeding at irregular intervals; allowing horses to bolt their food; irritants in the bowels, such as worms and indigestible food; bulky food; frosty water; sudden changes of temperature; and over-driving. Symptoms are:—Pawing and scraping with the fore-feet; looking round to the flank; attempting to lie down; lying and rising; rolling, sweating, and groaning, then an interval of ease. During attacks of the spasms the pulse beats are increased to as high as 70 or 80 per minute, but, when relief comes again, it gradually falls back to normal. *Flatulent Colic*.—Very different from the previous complaint. It is due to the fermentation of food or other matter in the bowels, caused by eating green food, frozen roots, and wet sheaves in harvest time. The animal shows all the signs of spasmodic colic, and in addition becomes greatly distended at the flanks as the disease progresses. If this bulging at the flanks is detected, and if the animal has been subjected to any of the above causes, treatment for flatulent colic should be adopted from the start. *Diarrhoea* is due to irritant indigestible food lying in the bowels. Intestinal worms are a fruitful cause. In foals it is often produced by putting them to suck while the mare is in a heated condition. *Worms*.—The three chief varieties are thread worm, pin worm, and particularly the red worm. The first is about 2½ in. long, and has a ring of tiny projections round the front part of the head, and thus it sticks to the lining of the gut. The pin worm can easily be identified by its curved shape. The red worm lives in the lumen of the bowel, and burrows and coils up in the lining also; often found with the thread worm. Symptoms:—Rubbing rump, and unthriftiness. *Founder*.—This is one of the most dreadful diseases the horse suffers from, occurring in all breeds, but most common among heavy breeds. Causes are over-exertion, pounding the feet on hard roads, over-feeding with grain, drinking cold water when heated, and standing in a strained position. It also follows such diseases as inflammation of the womb after foaling, inflammation of the bowels, and inflammation of the lungs. Symptoms:—The horse is usually so lame that it is difficult to get him to move. The hind feet are pushed far forward under the belly, evidently with the intention of relieving the fore-feet of part of the weight they have to bear. There is much fever, indicated by fast breathing, sometimes sweating, a rapid pulse, and a high temperature. Generally only the fore feet are affected. When the patient is made to move forward in a case of inflammation of the feet he appears to go on his heels, and, when backed, he raises his toes. After hours of standing the sufferer will lie down for hours, which seems to give relief. *Wounds*.—Any horseman can become reasonably adept at healing wounds by being careful and clean. Wounds are of various kinds. Sometimes they are great rents, caused by kicks, or barbed wire, or other sharp objects. Sometimes they are deep punctures. Sometimes they involve important joints or organs, such as the eye, and occasionally they penetrate the abdominal wall, or enter the chest cavity. The latter and more serious kinds should be treated by a veterinary, if possible. *Blood Poisoning*.—This condition is due to the entrance into the blood stream of minute organisms, which may have been present in a wound. These germs, in the process of living, evolve a poison which is carried through the system, altering the character of the blood and rendering it unfit to support life. Symptoms:—Shivering, colicky pains, prostration, abnormal breathing. The animal has a dejected appearance and expression. In some cases he lies down, and is unable to rise, but as a rule he retains consciousness and feeds occasionally. There is no curative panacea for the ailments of the horse; but kindness and sympathy are always a very great helping factor in preventing sickness.” (Secretary, S. Chynoweth.)

September.—Attendance, 8.

ENSILAGE.—Paper submitted by Mr. E. Koch:—“Ensiling a fodder or making silage consists in preserving green succulent plants so that they will remain green or semi-green and keep their succulence for a considerable time. Briefly, it is done by cutting the plant growth to be made into silage when very green and nutritious and storing it under pressure, usually in airtight receptacles of some kind, but sometimes in open stacks. The green forage to be preserved as silage should be cut while it is succulent and well supplied with live and active cells, and to ensure a good ‘cure’ the cut material should be put into the silo or stack whilst fresh and unwilted. The crops usually converted into silage, the cereals—wheat, oats, barley, and rye—are in the best stage for cutting from a week to a fortnight after the heads appear, and in this stage no matter how luxuriant the growth, they usually contain the correct

percentage of moisture to make good silage. The cereals can be converted into silage of good quality if cut before the heads appear, but more weight per acre is obtained by waiting, as the cereals continue to increase in weight until about three or four weeks after full bloom, although from then onwards a continuous loss takes place until maturity is reached. Two distinct kinds of silage are produced from all fodders suitable for storing as silage according to the method of manufacture followed. Anyone embarking on silage making activities must remember that only good fodder will make good silage and the better the fodder the better the silage made from it. Some weeds which are disliked by livestock because of the presence of many hairs or the possession of a disagreeable taste are considerably improved when converted into silage, particularly when they are mixed with better forage plants in the silo or stack. All farm animals which ordinarily consume pasture plants are attracted by the palatability of silage, and when it has been properly made eat it readily and in most cases do well on it. Dairy cows do very well on silage and immediately increase their milk production when fed on it. It is also a noted fact that cows fed regularly on silage remain in better health than those not receiving it, no matter what kind of feed they are provided with. Silage should never be distributed on the surface of the ground for milking cows, but fed to them in feeders of some kind. Silage can be fed to calves as soon as they start to eat foodstuffs. It is also highly recommended for ewes and also other sheep when there is a shortage of greenfeed. No matter how the silage is made no damage is done to it by birds or mice and there is no danger from fire." (Secretary, G. Heinrich.)

October 3rd.—Attendance, 15.

FIRE FIGHTING.—Paper read by Mr. L. Koch:—"The various methods of fire fighting depend entirely on the conditions under which they are to be used. As this district is immune from bush fires, attention should be directed to stubble and grass fires. On the outbreak of fire, the telephone is generally the means of raising the alarm, although the smoke generally serves on such occasions, especially in the prohibited season. Unless the fire is burning towards a good break, such as a fallow paddock or a road, attempts should be made to burn a break and the fire attacked from either flank. The beaters must make sure that every spark is out, for a change of wind may start another outbreak. If the fire is only travelling slowly it can—as a rule—be beaten right out, but if the reverse is the case, the beaters must direct their attention to the flanks and allow the front to burn itself out to the break. When the fire reaches the break, fighters must be in readiness to extinguish a fresh outbreak should sparks happen to blow across. This action may not be necessary if the break happens to be fallow, but in the case of a road with inflammable material adjoining, great care must be exercised. A shovel is an ideal tool for putting out flames, for if the leader is followed by two or three others the flames can be scraped out and the followers can put out smaller sparks, &c. Should the flames be of a fiercer nature, dirt can be thrown on them from several yards distant. Beating with a bag, besides being very tiring, is not very effective unless used correctly; the same applies to a bough. If used to their fullest advantage, very effective work can be done with both. A motor lorry fitted with a tank of water and pump and hose also play an important part in the fighting of fires. In addition to extinguishing fencing and stumps, which it does very effectively, grass and stubble can also be quenched. In reference to a burning stack, the only method is to tear the stack to pieces so that it burns out more quickly. The liquid spray pump is not very reliable, for if called for at a necessitous moment, any length of time after purchase the owner may find that it is empty (due to evaporation). Powder preparations are effective, although a limited quantity may only be available." (Secretary, G. Heinrich.)

WEAVERS (Average annual rainfall, 16.8in.).

August 7th.—Attendance, 10.

DAIRYING HINTS.—Paper read by Mr. E. Hergstrom:—"Contamination of milk starts from the time it leaves the teat of the cow and continues until the cream arrives at the factory and is pasteurised. Milk from a normal healthy cow is sterile, but immediately it comes in contact with the milk pail or bucket, bacterial contamination starts. It is not possible for the average dairy farmer to have his milk buckets sterilized, but the amount of bacterial contamination can be considerably reduced by scalding the buckets in boiling water after every milking. This is the first step towards good quality cream. It is absolutely necessary to have the separator clean and washed after every milking. The residue or sludge in the separator—if left over night—is very harmful to cream, in as much as it contains millions of germs which affect the quality of the cream and consequently the cream cheque. The most favorable temperature for the milk to be separated is from 96° to 101° F., if milk is separated at too low a temperature

there is an actual loss of butterfat which goes out in the skim milk. If milk is allowed to cool and then heated above 101° without direct cooling, the quality of the cream suffers, as it has the tendency to stimulate the bacterial growth and results in a loss in grade. Cream freshly separated should be kept by itself until it has cooled. A quick and effective way to cool cream, when a supply of water is plentiful, is to place the utensil in cold water and give it a few stirs. This is a very effective way of checking extensive bacterial growth. The cream should be frequently stirred from the bottom upwards to ensure even ripening. Keep the cream in an enamel bucket or basin until the day that it is to be despatched to the factory. Under no circumstances should the cream be kept in the can for any length of time; this has the tendency to make the cream metallic. Most of the metallic cream is caused through the cream being kept in containers such as kerosene tins, honey tins, &c. It may be possible to keep the cream in a clean new tin for a short while without getting the metallic flavor, but very soon the acid in the cream affects the tinning and the cream is exposed to the iron and absorbs the metallic flavor. The thickness of the cream should not be above 50 per cent. butterfat. Too thick a cream soon goes tallowy and cheesy, and is not possible to effectively stir. All cream received at the factories is reduced to a butter fat content of from 33 per cent. to 38 per cent. by diluting with water, consequently the fat globule is affected when the cream is too thick through excessive agitation during the process of pasteurization. Use a weak solution of washing soda when cleaning dairy utensils. Send the cream to the factory as often as possible. Seal the cans when receiving them back from the factory. Do not have the thickness of the cream over 50 per cent. butterfat. Do not use cans with rusty bottoms. Choicest grade cream is cream free from all taints and foreign matter, of smooth and even texture. It should taste sweet and clean. As the acid increases beyond a point the cream becomes first and finally seconds." (Secretary, H. Cornish.)

WESTERN DISTRICT.

BUTLER.

September 7th.—Attendance, 9.

CARE OF THE HORSE.—Paper read by Mr. N. Stewart:—"In this district under present conditions, with low market values and high producing costs, the farmer must look to the cheapest and most economical means of obtaining strength for the purpose of tilling the soil for the production of crops. In the past few years two means of power have been tried—mechanical and horse power—and with the results obtained the horse appears to hold superiority, for in most cases the tractor has either worn out, broken beyond repair at ruling costs, or too expensive to feed, but with the horse it carries on and our attention must be drawn to see how it can be cared for that it may give of its best. The first thing is the use of proper fitting harness. The team should never be asked to draw a load more than that which can be pulled comfortably, and it is a far better proposition to work extra time per day than to drive a team laboring under a load much too heavy. Overloading is the chief cause of sore shoulders, but in many instances a change of collar at the first sign of a sore or boil will change the position of draft on the shoulder and thus a nasty sore can often be avoided. The team must be fed and housed properly to keep it prepared for that which is expected of it. It should be fed and watered regularly, with a water trough outside the stable yard. Do not give the horses more feed than they will clean up at each meal. Little and often is a good feeding stable motto. Good Algerian oaten chaff with the addition of a little crushed oats is recommended, especially for the evening and night feeds and to turn them out to pasture during the nights and off days as soon as suitable feed is available. This can be obtained in most seasons by August by sowing during March or early April Early Burt oats with a light dressing of super on the burnt stubble land of the previous year's fallow. The horses must be provided with proper accommodation as a protection from the cold of winter and heat of summer. Tests have proved that horses do not require the same quantity

of feed if properly sheltered. The stable yards should receive such attention that the horses do not have to wade about in filth and damp to the detriment of their hoofs. A little shaping of the foot often prevents a part of the hoof breaking away, often causing lameness, especially during the hot summer months. Also attention should be given to the mane and tail, to see that no knots gather that may interfere with the comfort of the collar and harness. The tails should be drawn each year during June and July. This will give it time to gain proper length so that it will be useful to the animal to protect itself from flies. Leather fly switches should be affixed to all winkers for the summer months. The value of the hair the horse's tail produces if cut regularly each year, more than provides the costs of the switches for its face. The team should be fed $1\frac{1}{2}$ hours before being harnessed in the morning and taken to work at regular hours through the busy period. The driver should take particular care that the mouths of the horses on the reins are not jerked or to give any cause for them to jerk one another. This can easily develop into a bad habit and prove a serious detriment to the pace of the team. Use common sense when the horses are being classed for the teams; it is far better to work the steady horses in one team and the free walkers in another. The more patience the driver exercises the better teamster he proves and the animals regard him more as a **friend than a taskmaster.**" (Secretary, P. Lange.)

CUMMINS (Average annual rainfall, 17.77in.).

September 1st.—Attendance, 8.

FALLOWING.—Mr. H. Roberts read the following paper:—"These remarks are intended to apply to this district and to the older type of cleared land, but they can be applied with equal force to many of the surrounding districts. The depth of ploughing depends on the type and depth of the soil and the time of the year the fallowing is done. It is possible to plough 1in. deeper in June or July than in September or October, because the later ploughing will not consolidate. Generally the depth of ploughing in this district should range from 2in. to 4in., this being dependent at all times on some or all of the foregoing circumstances. Never plough in dry grass, the resultant crop is almost certain to be unprofitable. Do not plough sandy soils deeply. On the other hand, clay or Bay of Biscay soils may be ploughed any depth within reason, so long as the sour clay subsoil is not brought up. It does not hurt to bring a little of the clay subsoil to the surface in the loamy soils. This practice is known as 'tipping the clay' and is quite a good one if done gradually, for it slowly deepens the soil and thereby in time renders a greater quantity of plant food available. Fallowing should start as soon as seeding is completed. If seeding is late, it is generally a good paying proposition not to sow the last of it; let it remain as fallow. Try and finish fallowing by the first week in September. It may then be cross harrowed if weather permits, and it is then ready for the cultivator when weather and soil become suitable for the operation, which occurs with those first drying days in early or mid-September. If the weeds have made growth, sheep should trim them down before cultivation. The first cultivation should be completed before weeds have seeded. Give the sheep a day or two on the fallow now and then and the second working about the third week in October, and if done in the right weather it will leave the fallow in good order. Sheep should be put on fallow every two or three weeks to keep weeds in check. The second or last working should be done at a time that will kill stinkwort on fallow. It is worth an extra working to be rid of it. With fallowing done, say, in September, **only one working** will be necessary to kill weeds, but if it is desired to complete fallowing, it will be necessary to start as soon as possible after seeding. It is better to do less than the full programme of fallowing and have it properly cared for, than to do a lot of ploughing and not be able to keep weeds in check. It has been found in this district that crops as good, and in many cases better, can be grown on burned grass land ploughed up after rain and after harvest. This autumn ploughing, when it can be done, has the advantage of economy of operation, because there is not so much working to be done as on winter fallows and a certain amount of use can be made of the grazing. Autumn ploughing is dependent on rains falling at that time of the year, so that it is not a reliable way of preparing fallow. Nevertheless, in this district it is advisable to be prepared to do some autumn ploughing whenever autumnal rains give the opportunity. Autumn ploughing should be harrowed while still damp and every effort made to consolidate the soil, preferably by cultipacking. Failing this, the cultivator and harrows should be used after showers, so that a good germination of weeds will result with the first seeding rains." (Secretary, K. Trigg.)

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

August 29th.—Attendance, 6.

POULTRY ON THE FARM.—Paper read by Mr. A. E. Story:—"This paper is intended to deal with the subject not from a commercial poultryman's viewpoint, but as a farm sideline. In these times of low prices for our main products, such as wheat and wool one has to look for something to assist in bringing in a little ready money, and if a little attention and time is spent on poultry raising, it will greatly assist in this direction. One of our greatest drawbacks to this sideline is our great distance from market. In starting a flock of poultry it is necessary to consider which is the best breed of fowls to keep; breeding for the table trade is practically beyond us on account of distance from market, and there is only a very limited local trade; therefore, in starting a flock preference must be given to the egg trade. In this there are two breeds that are outstanding—the White Leghorn and the Black Orpington. The former is regarded by most leading poultrymen as the best suited for the egg trade on account of the quantity as well as quality of the eggs, but is of very little favor as a table bird. The Black Orpington is a very good table bird and an excellent layer, but the eggs lack the quality of the Leghorn in that they are of the small size and not so suited for export, which at the present time is the salvation of the poultry industry. To make poultry on the farm worth while, it is necessary to run a flock of about 300 hens; that gives sufficient eggs to ship to Adelaide during practically the whole of the year and thus obtain the highest prices obtainable, which is necessary if maximum results are to be secured. In starting a flock of poultry it pays a beginner for the first year to obtain all his requirements from some well-known breeder, either in eggs or chickens. Thus, he has laid down a good foundation right from the beginning, and with proper attention to housing and feeding should get good returns in eggs as soon as the young pullets commence to lay, which should be from five to seven months of age, according to the breed, heavy breeds taking longer to mature. Poultry where allowed a free range, as on most farms, do not take so much food, nor do they need the attention to housing when confined to yards, nevertheless it is necessary to prepare shelter for them, especially during cold wet weather. This can be done fairly cheaply by erecting straw sheds with sides thatched with broom bush in which nests can be erected for laying. Unless poultry are to be run on a fairly large scale it will not pay to erect elaborate houses, although there is no doubt that better results will result from better housing methods. Feeding a flock of 300 hens will take a good deal of grain and it is a good way to market it to return much more per bushel than selling wheat on the market and with very little extra outlay in labor. In a season such as has just been experienced there was much poor quality wheat which was practically unsaleable, or only so at a high dockage. The hen will return much more per bushel than can be obtained for the very best sample, although much better results in egg numbers will be realised if only good quality grain is fed. Last year I fed only first quality grain and obtained much better results than this year, when grain, which it was impossible to sell at any price, was fed to the birds. For the first six months of the year the hens paid me f.a.q. price for this wheat; during a good portion of which time about a third of the flock had not reached the laying age. In addition eggs were used for household purposes and birds for the table, of which no account was kept. Birds running on free range obtain a great amount of their food for themselves, especially when there is plenty of green feed, the only necessary addition to the grain ration is a little mash in the morning, to which is added meat meal. For the latter boiled rabbit is a good and cheap substitute. *Hatching*.—Much of the success of poultry raising lies in the hatching of chickens, for to have pullets laying when eggs are dear—from March until about June—the chickens must be hatched during August and September; in fact, I like to see some out by the middle of July, and with proper feeding the pullets hatched during these two months should be laying by March. Hatch heavy breeds first. To get chickens during these two months in any quantities artificial incubation must be adopted, because the well bred modern hen is a very poor sitter, especially the Leghorn, and to a lesser degree the Orpington, until she is in the second and third year. Keep a very few third year hens for best results. If it is decided to purchase an incubator, obtain one of a size considered suitable and of a proved make and design. I prefer the hot water tank to the hot air; it carries a more even temperature and is not readily affected by changes in the weather. If breeding pens are to be started for them select only birds that lay eggs 20zs. and over, and do not use eggs more than 10 days old; the fresher the egg the better the results; three or four days old is the ideal for hatching. The incubator needs very little attention. The main thing is to fill and trim the lamp once a day and turn the eggs once or twice a day; 10 dozen eggs take about five minutes to turn. When the hatch

is about to come out, it may be necessary to alter the regulator a little if the temperature has a tendency to rise too high; always keep plenty of moisture in the machine. Do not feed chicks for some considerable time after they are hatched; when they need food they will let you know by the noise they make. Always provide plenty of water, dry sand, and finely ground charcoal. All commercial poultrymen provide hot brooders for the chickens when they leave the incubator. We use only the cold system which is not so convenient for the young chicks, but after they are about a week old they seem to be quite all right so long as they are not allowed in a wet and cold place. Care and foresight, combined with good housing when young, will prevent many kinds of sickness. *Marketing Eggs.*—This is the greatest and most important aspect of this sideline, because its success or failure depends to a very large extent on the price that obtained for eggs sold. Price depends on quality and quality depends very largely on care and attention to smaller details. Market only clean shelled eggs, any stained ones should be kept for household purposes. So far as possible aim at producing the best grade, because during the export season eggs are paid for on a graded basis. The greatest trouble in forwarding to Adelaide is the distance from market and the number of handlings that they receive *en route*, which to a large extent affects the quality. Some of the eggs are over a week old when they come on to the grading floor." (Secretary, J. Wildman.)

GREEN PATCH (Average annual rainfall, 26.56in.).

September 28th.—Attendance, 10.

SUMMER FODDERS.—Mr. L. Sage contributed the following paper:—"One or other of the summer fodder crops can be grown in almost any soil provided it is well prepared and manured. Where cultivation during growth is not intended the best soil is one loamy enough not to run down and set but still sufficiently dense not to drift. In districts where winter rainfall is fairly heavy—an average of about 12in. for the three winter months—there is no advantage in early ploughing. August, or after a wet winter the beginning of September, is early enough if the land is kept well worked afterwards up to sowing time, which should not be until the latter part of October, because if the seed is sown before the soil begins to get warm a poor germination will result. Work the land well prior to seeding, drill deep if the surface is dry, sow late rather than too early, but do not harrow after the drill. This district is rather on the cool side in summer, so that crops that do not take too long to mature should be grown. I have tried a number of different kinds, and so far as an all round fodder Japanese Millet is the best. It comes on early, is quite safe to cut or graze at any stage of growth, if grazed judiciously will give several grazings during summer, and stock are very fond of it. Early Amber Cane is not as early as Millet, but is a good summer fodder crop, either for cutting or grazing, but like all sorghums is apt to be poisonous if used in an immature condition. Another variety that has done as well as Amber Cane is White Kaffir Corn. It does not grow so tall, but has more flag and a softer stem. It is just about as early as Amber Cane, and stock eat it just as readily. When drilling use a hoe drill if possible, it leaves the land more evenly ridged than the disc, and catches any light rain that falls. The seed must be mixed with the manure, but only as it is used; if mixed beforehand or left in the drill germination will be affected. A bag of high grade super to two acres will be sufficient on well-worked land. The drill box may be partitioned off, sowing seed through every third or fourth hoe, but run the super through all the hoes. If cut with the binder the machine should be run the same way as the drill; if only wide-spaced rows have been sown cutting across the rows would be rough on the machine. Japanese Millet is the best to sow for grazing; it can be grazed at any stage without fear of forage poisoning. Any of the sorghums should be allowed to just come into head, and when fed off or cut will keep on growing until the autumn. Millet seed is very small, and if a good germinating sample 4lbs. to the acre should be ample. Amber Cane, Kaffir Corn, and Sudan Grass seeds are much larger, and 7lbs. or 8lbs. of seed per acre will be needed. Any of these seeds can be tested for germination by placing seeds between flannel in a saucer, kept in a warm place, and moistened regularly. In less than a week germination should show out." (Secretary, C. Whillas, Port Lincoln.)

LAURA BAY.

September 5th.—Attendance, 18.

THE COST OF FARMING.—Paper presented by Mr. W. Edson:—"In this paper it is my intention to regard the farm as a sound business, and endeavor to prove that interest and depreciation must be fully charged on every item, and a sufficient reserve fund placed annually to meet adverse times which are inevitable. The total cost is somewhat surprising. I have taken our two farms of 903 and 734 acres respectively

as an example:—Capital expenditure—Land, £2,450 10s.; machinery, £890; 12 horses and 200 sheep, £350; total capital expenditure, £3,690 10d. Interest on capital, £179 10s. 6d.; depreciation on plant, £89; depreciation on 17½ miles of fencing, £35; wages for farmer, £300; wages for man and boy (keep included), £240; reserve fund, £150; total, £993 10s. 6d. Add £116 for super and £80 for bags, £1,189 10s. 6d., which, with 600 acres under wheat, would have to produce 12bush. to the acre to pay at 10s. per bag. As the district average is far below 12bush. per acre it is no wonder that farmers are finding it hard to make ends meet.” (Secretary, W. Edson.)

LIPSON.

November 4th.—Attendance, 10.

RABBIT DESTRUCTION.—Paper read by Mr. E. L. Barraud:—“It is everyone’s duty to do his share and thus reduce the heavy expenditure annually incurred in fighting this pest, and I submit the following methods as being cheaper and eventually having the effect of reducing the rabbits to impotency or wiping them out altogether in a few years. After harvest, say, February or March, a date should be fixed by the local authority, and the rabbit inspector should see that all start on that date, because simultaneous action is essential if success is to be obtained. Rabbits at this time take baits more readily, food and water are scarce, and one rabbit killed then is equal to many killed later on. Rabbits take moist baits better than any other at this time of the year and the use of raspberry jam and strychnine with changes to fruit or vegetable baits are recommended. A level teaspoonful of powdered strychnine to 2lbs. of raspberry jam is the best amount to use. More makes the bait unpalatable and less is not enough. Baits should be placed about 12ft. apart on a flat stone or piece of wood in a newly-drawn furrow and should be about the size of a 3d. piece. Phosphorus poisons for summer use are not favored; they dry quickly and there is a danger of fire, but where grass is very scarce and this poison is used, it is well to rub a little oil of aniseed on the hands before handling the baits. When green feed is available, poisons are of little use and smokers or cynogas can be used in the burrows. After being smoked out the burrow is dug or ploughed out the next day; that does away with it, as the rains will set it down hard again, when no attempt will be made to open it up for a long time. Should an attempt be made to open a hole, a trap set in the opening soon puts a stop to this. About 60 traps can be used with good effect on an averaged-sized farm. Where a creek runs through a section this makes matters more difficult, but, if after a heavy rain all burrows in the vicinity are gassed or smoked out, a lot will be killed as they go there when washed out of the waterways. In summer a few spoonfuls of shale cynogas thrown into the worst cracks in the creek bank will cause the rabbits to move temporarily elsewhere, and a couple of men with crowbars for a day or so can smother a lot in the cracks when the ground is dry. Where the ground is of a sandy nature, ploughing in can be done in summer time with good effect. Trapping from the farmer’s viewpoint is not successful; it leaves the small rabbits and continues the pest. In conjunction with the other methods it is good. If the foregoing methods are used there is little doubt that in the course of a season or two it will not be necessary to spend the large amount of money which is now being spent in spasmodic efforts to rid farms of rabbits. The keynote of success is simultaneous action, and in no case should a person relax his efforts when rabbits have ceased to be an active danger to feed and crops.” (Secretary, M. Barraud.)

MALTEE.

October 5th.—Attendance, 8.

DESTRUCTION OF FOXES.—Paper contributed by Messrs. V. and P. Schwarz:—“During lambing season the careful farmer is ever on the alert to guard against losses incurred by foxes. *Poisons.*—Strychnine in two forms can be used. The crystal form is to be recommended, but the soluble form may also be used with good results. The correct amount of crystals to be used for a bait may be described as being sufficient to cover a 3d. piece. *Preparation of Bait.*—The parrot is a favorite bird for the fox and makes a very attractive meal. Other baits can be prepared from rabbit, liver or heart of sheep, or a thick clot of blood from sheep killing. A satisfactory size of the bait is about 1in. square. If the bait is too large only a harmless portion may be eaten. A dead sheep or lamb can be made a tempting meal for the fox when poison has been added, but in this case it is quite likely that birds may carry baited pieces over the paddocks, making it unsafe for dogs. When preparing baits, avoid handling them. An old fork often proves very handy in assisting in the preparation of the baits. *Laying the Bait.*—The best time to make a trail is immediately following a shower of rain. In laying the trail, a carcass of a sheep is very suitable. Poisoned baits should be placed at regular intervals along this trail, and to facilitate checking up next morning

" mark should be made indicating the location of each bait. It is advisable to cover them with a little soil to detract the attention of birds during the day. *Other Methods of Catching.*—Fasten a schnapper hook to a piece of rope and tie to a branch of a tree so that the hook is situated about 4ft. above the ground. Place a parrot firmly on the hook so that when the fox jumps for the bird he is caught like a fish. *Snaring.*—Rabbit traps can also be used, but results are not very encouraging. Do not fasten the traps very firmly, because foxes are quite capable of pulling off their toes, enabling them to escape. A better way is to tie a weight to the trap so that it can be dragged by the fox without his parting company with the trap, because once a fox escapes in this manner it has been said that you would need a very salty method to again make him your victim. *Preparing Skins.*—Commence by slitting the back of the hind legs down to the top of the tail and skin them. Hang up similar, to a sheep and continue cutting along the centre of the tail and pull off. Take care not to tear or damage the skin. There are two methods of skinning: (1) by slitting the belly, and the other of making a sleeve, which is practically the same practice adopted in skinning a rabbit. The sleeve method is easier and quicker. When the tail is finished, the skin only has to be pulled down over the body to the front legs, which are pulled out. Proceed further to the lips, cutting them and taking off completely. *Pegging Out.*—First, a nail is inserted through the nose and firmly driven into a door, which serves the purpose quite well. Next the bottom lips are stretched and firmly fastened—sloping upwards—after having pulled both sides evenly. If the skin is needed for a fur, it should be stretched as long as possible. For sending to market the skin should be stretched as square as possible. If the skin is wanted for a fur, hammer a few nails in the top of the tail stretching it tight. Afterwards stretch the back legs slightly sideways, fasten the front one straight out, and finish by tightening the remainder of the loose places, such as the back, brisket, and widening the front legs to complete it. To make a square skin—after nailing the bottom lips, nail the back legs, then the front ones; next, the back, going down to the tail, and finishing as before. *Marketing.*—When the skins have dried sufficiently during a period of one or two weeks, the next problem is that of finding the best market. They may be sent to the auction sales or direct to the fur companies. The auction sales should be better, because the skins are sold under competition between the various fur companies, and this always tends to ensure bright prices." (Secretary, P. Schwarz.)

MOUNT HOPE.

October 9th.—Attendance, 7.

FENCING.—Mr. W. Vigar read the following paper:—"The best time of the year to fence is just after seeding. This is generally a fairly slack period, and in the light coastal soils one does not have any trouble with sand running into the post holes and half filling them before the posts can be put in position. Also the rains that follow will consolidate the earth around the post so that by summer time it will be quite firm. The boundary fence is the most important fence on a farm. The law with regard to boundary fences is important. Under the Act one is required to erect a fence capable of resisting the trespass of cattle. This fence may be either of plain or barbed wire. Unfortunately the Act does not compel any landholder to erect a rabbit proof fence, although the Vermin Act compels him to destroy all vermin on his holding. If all boundary fences were rabbit proof there would not be so much trouble with rabbits. The liability of adjoining landholders with regard to boundary fences is also dealt with in the Fences Act. Where two properties join without a road between them both owners are liable for the cost of the erection of such a fence in equal part. One point is worthy of particular notice. Should one owner desire to erect an elaborate fence which the other owner does not believe to be justified under the circumstances, the first owner may erect the fence, but cannot claim for one-half of the value of it, but only one half of the value of a "sufficient fence" within the meaning of the Act, or one-half of the cost of the type of fence mostly erected in the locality. If a fence of five plain wires and one barbed wire is the usual type of fence for boundary fence purposes, and one farmer wished to erect a rabbit-proof fence, he could only claim for half cost of the six-wire fence above specified. At the same time, if both owners agree to erect a rabbit-proof fence there is nothing to stop them from so doing. As most places in this district are surrounded by roads a perusal of the section of the Act dealing with the liability of persons using the fence on the further side is worth while. While the law does not expect the owner on the further side of the road to contribute to the cost of the erection of the fence he has to pay the owner of the fence interest at the rate of 8 per cent. per annum on the value of the fence for so long as he shall use it, and to contribute to half the cost of any repairs. The value of the fence means the value at the time the adjoining owner first uses

it, and not the cost of the fence when first erected unless, of course, the adjoining owner uses it. Since, from the farmer's point of view, the law is not interested in any other than the boundary fence, all other subdividing fences are left entirely to the discretion of the farmer. All permanent fences should, if possible follow section lines. If a good rabbit-proof fence is erected around the boundary it is not necessary to have any netting on any subdivision. These could be ordinary sheep proof fences of five plain wires and one barbed. This method of fencing would be cheaper than the usual haphazard method of putting netting around part of the boundary and on some subdividing fences and sheep-proofing other parts. A few small paddocks close around the homestead could be netted even if the boundary was, too. This would keep rabbits and poultry away from any special fodders or trees. *Height of Fences.*—The height of a fence is of considerable importance and, like the type, varies with its uses. For a good type of netting fence 3ft. 10in. or 4ft. is much better than one 3ft. 6in. high. With a barbed wire strained tight on top of the posts—not tied alongside—stock will not reach over and damage a fence to anything like the extent they will if the fence was 6in. lower. Even for a sheep proof fence it should be as high as possible without getting the wires too far apart or using more than six wires. With a high fence one would have to sink the post holes a bit deeper where there was no rock. *Barbed Wire.*—Although barbed wire is condemned by some people it is a very real necessity for fences. The more barbed wire one can use within reason around the homestead the better for all outside fences. Stock soon get to know that it hurts, and as they undersand that they cannot go just were they like about the place they do not get the habit of breaking down fences, with the result that when they are turned out into the bigger paddocks they do not worry the fences. An ideal fence for small paddocks is one with two barbed wires above netting and two plain wires to tie the netting to, and one to be put about half way between that and the ground. This type of fence is easier to keep tight than a six-wire fence. All fences should always be kept strained tight. This keeps them stock-proof, and takes a big load off each individual post, besides keeping the much neater in appearance. If good gum strainers are used local ti-tree and sheoak posts will last half as long again. It is not necessary to have posts too close together; about 12ft. apart for small paddocks and 15ft. or 18ft. for larger paddocks should be satisfactory. All fences should be carefully lined out before starting, and straight, sound posts used. A medium-sized post is preferable to either a thin, spindly one or a heavy one. Holes should be bored with care, otherwise a neat lot of posts will look very ragged when the wires are pulled in. Care should also be taken to keep the tops of all posts level. Neat, well put up fences improve the appearance of the farm, and it pays in more ways than one to keep all fences in as perfect a state of repair as possible. (Secretary, A Myers).

PINBONG,

September 2nd.—Attendance, 12.

SELECTION AND CARE OF SHEEP.—The following paper was read by Mr. E. Kammermann:—"Select ewes that are clean faced and without tail wrinkles, and large frames with long roomy bariels. The wool should be of a fine bright texture. Dingy yellow and heavy woolled sheep are more liable to blowfly strike than the former. The next task is to select the sire. Again avoid face and tail wrinkles. It is admitted that a sacrifice of a certain amount of wool is made by breeding away from wrinkles, but the object is to avoid more serious trouble in the form of grass seeds and blowfly strike. If sheep—and particularly lambs—are badly affected with grass seeds—and this frequently happens with the face-wrinkled ones—their growth is retarded, the constitution weakened, and they become a prey of the blowfly. Having selected the type, the next point is to decide the number that can be successfully fed. Always remember that half the breeding goes down the neck, and that two well-fed sheep will possibly produce more wool in value than double the number of ill-fed animals. The blowfly pest has been engaging the attention of scientists for some time, but up to the present no effective method has been evolved to deal satisfactorily with the pest. I have tried many oils and antiseptics, and the only solution that has proved in anyway successful has been phenyl. If a sheep is struck, take the shears and clean away the affected parts, and then treat with phenyl—1 part to 5 parts water. This is a cheap and effective remedy. The sheep will immediately recover and the wool will not be damaged. Prevention is better than cure, and a general practice should be made of inspecting the flock at least once each week. Do not wait until the damage has been done, but clean up any that appear dirty and stained. If a sheep is badly struck, shear it completely and treat the affected parts as stated before. A sheep will rarely get badly struck until half-woolled and another short fleece will have grown by shearing time. The two sound

short-staple fleeces will be worth more than the one of broken dead wool which would have resulted if only the affected parts were shown. By this method it is possible to prevent another strike and minimise the danger of having others struck." (Secretary, C. Scholz.)

WALLALIA.

September 20th.—Attendance, 8.

HAY MAKING.—Paper read by Mr. D. Coxon:—"Hay should be cut early enough to be stacked before reaping begins, which means that an early wheat must be sown as early as possible. Early oats are better for hay, but a mixture of these two cereals makes an excellent fodder. Wheat for hay should be cut when it starts to turn a brown color. Oats should be cut for hay when the straw turns purple. If a large area is to be cut start slightly earlier, because oats ripen very quickly, and then much grain is lost by shaking out. The binder is the best machine for cutting; it saves much time and labor, and it is easier to work in good years. In this district there are many seasons when a grass mower and hay rake can be used to advantage. In good years it is a good plan to cut an extra stack. Hay can be stooked almost any time after binding. The stooks should stand at least nine days after being cut before being carted to the stack. When ready to build the stack use plenty of dun nage for the foundation. In some rough country it is an advantage to cut with the mower, because it has a better clearance than the binder. If the hay is not to be chaffed loose hay is better on account of it being mixed; the binder places the heads all one way, and this fed loose means more waste. When building the stack the main object is to keep out the wet, so that the middle must be kept higher than the edges." (Secretary, C. Zippell.)

YADNARIE (Average annual rainfall, 14.09in.).

October 3rd.—Attendance, 5.

THE PERCHERON HORSE.—Paper read by Mr. M. H. Way:—"The Percheron is about the oldest heavy horse known and it is difficult to understand why this breed has not obtained a better footing in Australia. In other parts of the world it is in the ascendancy. France is recognised as the home of the Percheron, and 90 per cent. of the heavy horses there are Percherons, about 50 per cent. in Belgium, and the same in Denmark. Two-thirds of the horses in the United States of America are Percherons. These countries are considerably older than Australia, and have paid attention to procuring a horse for heavy work that thrives under their climatic conditions. There is no horse that can do the same amount of work on the same amount of feed as the Percheron and the breed is very tractable and intelligent. The champion heavy gelding of the world is a Percheron. In America there are six Percheron horses owned by the Armour Company. After winning the American International Championship they were sent to the International Horse Show, Olympia, England, where they took everything before them. Apart from this, one of this team of six was selected as a perfect specimen of a heavy gelding. He was 15 years of age and had been working on the streets of Chicago for nine years. I predict that in the future most of our horses will be Percherons, because they will stand up to droughty seasons, more especially on the West Coast." (Secretary, E. Spriggs.)

September 28th.—Attendance, 10 members.

CARE OF THE FARM PLANT.—Mr. T. Stoeckel read the following paper:—"Every care should be taken of the horses. Do not expect six horses to do an eight-horse job. See that all harness fits perfectly, and give it at least two oilings per year. Ill fitting harness is the main cause of sore shoulders. Feed liberally and regularly, as a horse cannot do a day's work on insufficient feed. Groom them every morning, and examine the shoulders. Sores can often be prevented if attended to in time. When starting any implements see that everything is in order and all parts and bolts tight. Use a good oil, and see that bearings and wearing parts are properly lubricated. If a bolt breaks replace it with one of the right size. When finished with an implement put it under a shed and clean off all grease and grit. Any worn parts should be replaced so that the machine will be in order when next wanted. A small blacksmith's shop on the farm, and a few handy tools will prove a great saving of time and expense." (Secretary, G. Spencer.)

October 26th.—Attendance, 13.

MICE PROOFING A HAY STACK.—Paper read by Mr. R. Schultz—"Dig a trench 9in. to 1ft. deep and 4in. wide 2ft. away from the stack. Fill it with cement concrete, and while the concrete is still wet drive iron droppers into the centre on which to bolt the iron. The iron should be of the flat galvanized type, 3ft. high, and have a slant outwards of 45 deg. This will stop mice from crawling up, and should there be any in the stack they have a way of getting out. When not in use, the iron may be taken off and stored until wanted again. The concrete is to save putting the iron in the ground, and at the same time stops the mice from digging through. If desired, a toe may be put on the bottom of the concrete on the outside." (Secretary, G. Spencer.)

KI KI.

August 12th.—Attendance, 14

POULTRY BREEDING.—Mr. Griffiths read the following paper:—"Poultry keeping continues to expand in country districts, but there is need for the adoption of better methods in the housing of the birds. In many districts the birds are allowed to roost on fences and trees, and this practice encourages diseases and parasites. Adequate housing in which the birds can be locked at night should be the first essential, and nests should be arranged in the houses and the birds induced to make use of them; this will facilitate the gathering of eggs. While the pullets are growing it is advisable to grade them so that only the most promising are brought into the laying houses. Any bird that shows signs of weak constitution, or is lacking in the points necessary in the layer, should be discarded. The following points should be observed:—None but sound healthy stock should be bred from; regular and proper feeding; sanitation in houses and yards; no chicken should be fed until 60 hours after being hatched. Chickens should remain 24 hours in the incubator before being removed to the brooder, which should be heated to 100° and after a few hours lowered to 90°, then gradually to 70°. Any sudden change to cold or heat is fatal. All chickens should have access to plenty of fresh water and all vessels boiled once a week. Green feed is also essential. To go in for poultry in a big way means money for wire, iron, and wood, and one person's labor. Green food is as essential as clean water. Every endeavor should be made in penning the future layers to secure sufficient pullets of the one hatch or age to make up a unit. A week or two difference in age will not prove a drawback, but a matter of several weeks will affect both classes. Heavy and light breeds should not be housed together if it can possibly be avoided, because the light breeds will be bullied and will not obtain the quantity of food essential for their bodily upkeep and egg production." (Secretary, R. Cooley.)

LONE GUM AND MONASH.

September 5th.

FROST PREVENTION.—A special meeting of the Branch was held to discuss arrangements for preventive measures against frost. Reports of the work of the central committee were given by Messrs. R. Nixon and M. Nicholas. It was decided to adopt the suggestions of the central committee, and a local committee, comprising Messrs. Traeger, Telfer, Ellis, Cocks, Maddern, Soderberg, Elleway, Whitelaw, Thomas, Brown,

L. Bollenhagen, McLaren, Barnes, and Lock, was appointed. At a subsequent meeting of the committee, to which Mr. Maddern was elected chairman, arrangements for carrying out the scheme were made. Definite data will be kept throughout the frost danger period, and "smudging" will be tried out on a systematic scale. Wet and dry bulb thermometers have been provided, from the readings of which early warnings of danger will be given at 9 o'clock at night. The committeemen who represent the groups of settlers in the various low-lying hollows of the district will be notified of the danger, and, having a roster made out, two growers will then keep watch on their dry bulb thermometers. Should the temperature drop to 31 degrees, all growers in the group will be called out to stand by, and then should it drop to 30 the signal would be given to light the smudge fires and so create a dense blanket of smoke, with the idea of preventing the radiation of further heat, and so it is hoped prevent or minimise frost damage. Various methods of creating the smoke will be adopted, chief being the use of residue from the Cobdogla pumps mixed with old stems, &c., and the use of oil pots which will burn crude oil or tar. A definite set of observations will be kept, from which it is hoped quite a lot of useful information as regards the efficacy of the idea of smudging will be obtained. It is known that some people have consistently carried out this method of frost prevention to their own satisfaction, but no detailed collective records have been kept, so the scheme will, in the case of a frost season, be properly tried out on a community method, from which definite results one way or the other may be expected. (Secretary, R. Telfer.)

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

August 19th.—Attendance, 29.

RECREATION ON THE FARM.—Mr. H. Kempe read the following paper:—"Recreation is the reanimation and revival of a person's exhausted strength and spirit, and the refreshing from physical weariness, and any relaxation that will serve to enliven, amuse, entertain, divert, and cheer an individual. A man's form of recreation is—apart from climatic influence—governed to a great extent by the nature of employment that he follows. A person of sedentary work and habits naturally indulges in vigorous outdoor games, such as tennis, football, &c. The person, on the other hand, whose work takes him constantly into the open spaces, one might expect to seek diversion indoors, by visiting theatres, playing billiards, cards, &c. It behoves the farmer, as well as any householder, to make his home as attractive as possible for his family. He naturally wishes to keep the boys and girls on the farm, and he will find little difficulty in doing this if the home is sufficiently inviting to the young folk. Suggestions to make the home attractive would be such acquisitions as a good and comfortable home, motor car, wireless, some other form of music, *e.g.*, piano, violin, &c., games of cards, and a variety of wholesome reading. One often observes that rural boys and girls are keen on tennis and cricket, and the erection, therefore, of tennis courts and cricket pitches should receive due consideration. The practical and systematic arrangements of out-houses, stables, and sheds, the modernness of implements and utensils, also play an important part in making the farm more alluring to the young. The cultivation of an interesting hobby gives no end of pleasure and recreation. This form of relaxation and enjoyment is open to everybody, and also to all members on the farm. The father, for instance, may be devoted to wireless; the mother to the raising of prize flowers; the son addicted to electricity or the rearing of show poultry or animals; the daughter may develop a fancy for intricate needlework, confectionery-making, baking, &c. Without hobbies I should think life hardly worth while, and I can honestly recommend a good hobby as one of the finest and purest sources of lasting recreation." (Secretary, C. Altmann.)

October 28th.—Attendance, 23.

TANK CONSTRUCTION.—Mr. O. Aesche read the following paper:—"In selecting a site for the tank be careful not to choose a place on the lowest part of the watercourse, otherwise when the tank is full the water will not be able to escape. If possible the site for the tank should be hard ground. Only the best material should be used in construction work, and all mixing done on clean, hard ground. The walls should be made about 2ft. higher than the surrounding ground and backed up with the earth that has been thrown out of the tank. This will keep the water away from the walls. A good material is concrete, made of 8 parts rubble to 1 of cement, making the walls 4in. thick, using hoop iron or old wire all around every foot or so of the walls and hooking it at the corners to prevent it cracking. For the plastering use 6 of coarse sand to 1 of cement, finishing off with a fairly thick cement wash that can be applied with a whitewash brush. For the roof, pines covered with broom bush will be much

cheaper than timber and iron. In a waterless district more tanks should be built because long dry spells and droughts recur and water carting is the job for the day once more. It is also advisable to make provision for a water supply near the homestead to be able to grow vegetables and fruit and flowers. A tank holding 8,000galls. will cost approximately £12 in cement in addition to labor." (Secretary, C. Altmann.)

August —th.—Attendance, 15.

DAIRY COW JUDGING.—The following papers were read by students of the Strathalbyn High School:—(L. Oakley):—"The most commonly used cows for dairying purposes are the Jersey, Australian Illawarra, Milking Shorthorn, Friesian, Ayrshire, Guernsey, and Red Poll. The following points are looked for in judging a dairy cow:—1. Forehead: broad; this indicates brains and intelligence. 2. Horns: fine and shapely, which indicate good appearance. 3. Eyes: large, with a placid expression, which show alertness and happiness. 4. Muzzle: broad, strong and deep. 5. Neck: fine, shapely, and neatly joined to head and shoulder, which adds to general appearance, and shows lack of fat. 6. Jaws: wide and strong, which shows good feeding powers. 7. Shoulders: broad, flat bone, and blending into body. 8. Foreleg: fine bone, straight and short, indicates good appearance and strength. 9. Brisket: light, as there should be no extra meat. 10. Ribs: long, broad, wide apart, and well sprung; these show good digestion and breathing powers. 11. Barrel: long, well hooped and deep, shows plenty of room for digestion. 12. Flank: thin and arching. 13. Milk veins: large and prominent; these show a good dairy cow, because if the veins are large it shows that the cow can produce a good quantity of milk. 14. Teats: evenly placed, pointing down, convenient size, fairly square at bottom, and should give a free flow of milk when squeezed; if they give a free flow of milk they are easier to milk. 15. Udder: it must be capacious, well balanced, carrying well forward evenly, full at rear, not fleshy, firmly attached to body, and udder veins well developed, and plainly visible; this shows a good milker. 16. Tail: long, fine, set on level with back, and tapering, which adds to general appearance. 17. Thighs: thin and long. 18. Escutcheon: wide on thighs and distinctly defined, which shows richness. 19. Pin bones: prominent and wide apart. 20. Rump: long, broad, and level; these show general appearance. 21. Hip bones: prominent, level and wide apart, indicate easy ability to calve. 22. Back: broad, strong, and straight. 23. Style: alert and mild; this indicates a good appearance and good temperament. 24. Withers: fine, thin, sloping out to shoulders. 25. Skin: thin, loose and mellow, which shows good health. The judge also looks for a free walk, and a docile animal. The cow should be of a calm nature, not easily upset, or it will vary in health and milk yield, due to over-excitement. The general appearance of the animal denotes a high class and economical dairy cow. To judge a cow, begin at the head, from there to the forequarters and body, and then on to the hindquarters. The importance of comparison is to find out a good and bad cow, to ascertain which cows to keep and which to get rid of."

OBSERVATION ON CALF PROJECT (Lewis Thring):—"In February I began my project, intending to feed some calves on skim milk, and others with the same amount of milk, with a concentrate added. I am rearing seven calves. The first pair were born in February, one a few days later than the other. I fed one on plain separated milk, the other on the same amount of milk, which was about 1½galls., and in it I put, on the average, about 4ozs. daily of meal mixture, which consisted of 1 of linseed meal, 2 of crushed barley, and 2 of crushed wheat. The calves were fed twice daily. I found in this pair that the meal did not make much difference until the calves were about 2 months old, but after this time the calf receiving the meal is growing away from the other calf. The calf evidently liked the meal, because he always ate the meal that was left in the bottom of the bucket after he had finished his milk. When they were about 4-6 weeks old I began feeding them on chaff and 3 double handfuls of crushed barley to every kerosene bucket of wheaten chaff. This they ate readily till I let them out on the grass at 3 months old, when I stopped giving it to them. I

bought 3 more calves at the end of June. Two I fed on meal mixture, and one on the plain separated milk, and I gave them all the same amount of milk. These I let run in a paddock, with a shelter shed for them. I found these did better than those before, which had been penned. However, they scoured slightly, due to the green feed. In this trio those fed on the meal went ahead straight away. I have secured another pair of calves, but as I have only had these for a short time I cannot see the difference. It has cost me £2 19s. 2d. to feed the calves with milk at 1d. per gallon, the meal at 1d. a lb., and the linseed at 2d. a lb. So far my project leads me to think that housing is no advantage, provided they have a shelter when it is cold and wet, and that a concentrate should be added to separated milk to give them a complete food."

PEA GROWING (Colin Stacey):—"The pea plant, or plants with pods, have the power of putting nitrogen into the soil by means of their roots. The roots have nodules on them, caused by the bacteria which fix the nitrogen. The plant has an irregular stem, compound leaves, and large stipules, and the stem usually breaks down under the weight of the plant. The flowers are white or purple, and occur singly or in clusters at the ends of the stems or branches. There are not many varieties of field peas, the Early Dunn and White Brunswick are the most commonly known. Other varieties are White Elephant (large white peas), Blue Prussian (blue peas, and irregular shapes), Black-eyed Susans (white, with black spots), and Partridges (black mottled skin). The climate for peas is a fairly heavy rainfall, not much less than 20in., cool spring weather, and warm weather to harvest them in. The climate is more important to peas than soil, but peas like soil with plenty of lime and loamy soils of high fertility. A good rotation for peas is fallow, wheat, peas, and wheat—that is, in a place of 20in. rainfall. Unless much care is shown in cultivation, peas leave the land in a weedy condition. Peas should not be grown on fallow, because they put on too much growth and not enough peas. The soil should be ploughed in autumn, and cultivated and harrowed twice before seeding, and will also do well ploughed up and sown immediately. Seeding should be done in June with about 1½ bush. to the acre. Super should be sown at about 180lbs. per acre in 20in. rainfall districts. The best way to harvest peas is with an ordinary header harvester, fitted with a pea-attachment in front. It is almost not worth the labor to tramp them out and put them through the winnower. Pea stubble is of great use for producing fat sheep."

At the September meeting of the Branch, which was attended by 8 members, Mr. J. Bradford presented a paper, "Sheep Husbandry." (Secretary, M. Pearce.)

CLARENDON (Average annual rainfall, 32.89in.).

October 2nd.—Attendance, 12.

THE LIVE PIG TO BACON.—Mr. L. C. Spencer read the following paper:—"The pig 1 favor for bacon for home consumption is secured from a Tamworth-Berkshire sow crossed with the Large White Boar. This class of pig will give a good distribution of fat and lean. The pig that is required to-day for export trade and also for the home market is one of this type. The pig should be reared on the farm, and from produce grown on the farm. The man on the land must economise, and a pound saved is a pound made. The Tamworth-Berkshire has a nice bright skin, and, when dressed and crossed with the large White, the carcass always cleans easily, which makes it possible for amateur butchers to make a nice job of slaughtering and dressing. The pig should not be fed on the day of slaughter. The pig should be caught, placed on his back, front legs held back tight, straddled by the holder, with his feet close in to the sides of the pig. The sticker takes hold of the lower jaw, inserts cut, turns over the knife, and makes a straight line to the tail. **Scalding.**—Take 3 buckets of boiling water to 1 of cold in a convenient tub. First immerse the head, which is the most difficult part to clean, and keep it moving until the skin and rough pieces peel off in the tub. The meat is then taken on to a stool, cleaned thoroughly, hung up, and dressed, and left overnight to set. In the morning cut the carcass down the centre, and joint to suit requirements and the curing tub. The brine is prepared just strong enough to float an egg:—½lb. salt petre is added to 100lbs. pork, one-third of the amount of salt being used as a guide to the quantity of sugar. The pork should be shifted from the top of the tub to the bottom several times, each time sprinkling a little salt over the visible meat. It is left here for 14 days, then taken out, placed in a tub of water for 24 hours, and then hung up to dry. If conveniences are on hand to cure in full sides, it is necessary to use a brine pump, and inject the solution into the thickest places and around the bones. To prevent the skin and flesh from drying hard, the application of a little olive oil will help; it also improves the appearance if smoking is required. Many prefer the smoked meat after they have acquired the taste. That is hardly necessary for home consumption." (Secretary, T. Brooks.)

CURRENCY CREEK.

September 4th.—Attendance, 8.

CLASSING THE FARMER'S CLIP.—The Hon. Secretary (Mr. D. Jeff. Gordon) read the following paper:—"The farmer owning 500 to .600 sheep should pay just as much attention to the "get-up" of his clip as the station owner. It is not necessary to make as many classes, but he must be as careful, for farmers' clips, being small, do not bring as much competition as the stations', and if badly got up are only taken by speculators at very low prices. Shearing should be done on a clean floor, the fleece picked up carefully, thrown on the rolling table, and skirted regularly. Where the sheep have been breeched only the burry and dirty edges need be taken off; the sides should then be turned in, one slightly more than the other, and the fleeces rolled from breech to shoulder. In Merino, the extra heavy, matted, or discolored fleeces should be kept separate. In Crossbreds the extra coarse wool should be removed and put with the Lincoln or whatever breed was used in the crossing. It is advisable to pack

pieces, bellies, stains, and locks separately, even if they have to be put in bags, for mixed lots never bring their full values. As regards lambs' wool, anyone owning a hundred or so should take the clean wool from the fleece and pack it separately. The farmer should keep as near to one kind of sheep as possible, for by so doing he does away with so many small lots and receives better results."

CURRENCY CREEK.

November 6th.—Attendance, 9.

FIRST AID TO THE INJURED.—Mr. L. Collett^{1st} read the following paper:—"A first-aid man's work is not to take charge of serious cases and expect to carry them through without medical assistance; his work ends where the doctor's begins, i.e., his job is to do what he can for the patient until a doctor arrives. It is first necessary to know something of the structure of the body and the functions of the more important organs or systems. (1) *The Skeleton*, or bony framework of the body, gives the body its shape and firmness, affords attachments for the muscles, and protects the internal organs. (i) The skull holds the cranium, jawbones, and eyesockets. (ii.) The backbone, spine, or vertebral column, with the muscles or ribs attached, gives the power to straighten, or bend and twist, and contains the spinal column or cord. Between the bones of the vertebrae are cushions of tough cartilage or thickly packed gristle giving the power to land from a jump without jarring the base of the brain. (iii.) The ribs, of which there are 12 pairs, are terminated at the front by cartilage, the upper seven pairs being joined to form the breastbone. (iv.) *The Upper Limbs.*—(1) The shoulders are the collarbones and shoulderblades. (2) The arm is hinged at the shoulder by a ball and socket joint, at the elbow by a perfect hinge, and at the wrist and fingers by a series of small hinged bones, 27 in number. (v.) *The Lower Limbs.*—(1) The pelvis is a basin-like mass of bone attached to the lower part of the spine. (2) The leg consists of the thighbone, kneecap, and shinbone, with the ankle and foot at the far end. (2) *Muscles* are the red flesh of the body, classified into two groups—voluntary and involuntary. The voluntary muscles are found chiefly in the arms, legs, neck, and on the trunk surface. They are moved by will power. The involuntary muscles are found in the heart, lungs, stomach, and intestines, &c. They keep on with their work whether we are waking or sleeping. *Fractures and How to Mend Them.*—The most common form of fracture is by direct violence as in a broken leg, arm, or rib, &c. But very often a person fractures a bone by indirect violence, such as alighting on the feet from a jump and fracturing a thighbone or knee. Again, muscular action might break in two the kneecap or arm bone. A fracture may be simple, where a clean break has occurred, compound where a bone has been splintered and protrudes through the skin, or complicated where a broken rib may enter into a lung—essentially a job for a doctor. If the bone of the upper arm has been broken midway between the shoulder and elbow, first make a set of three splints—one to fit from the armpit to the elbow (inside), the others from the shoulder to the elbow (outside). Next take the elbow in one hand and the broken place in the other, and pull until the two arms are of equal length, press the break firmly into place, put on the splints, and bind securely with two bandages, one above and one below the break. This will cause some pain, so be as gentle as possible. The same method should be adopted for all breakages of the limb bones. The two bones in the forearm are straightened by turning the palm upwards, and the shinbones are straightened by holding the two feet together. To make a sling for the arm, take a piece of cloth about 1yd. square, and make a triangular bandage by placing together the two far corners. Place one point up the arm at the back, the second around the neck from the far shoulder, passing the cloth under the elbow and forearm across the chest. Take the third point and carry it to the shoulder nearest the break, and tie a reef knot on the shoulder. If a rib be broken, place two broad bandages around the body and tie firmly with the centre of each immediately above and below the fracture. The lower bandage should overlap the upper, with the knots on the opposite side of the break. To make a broad bandage, take the apex of the triangular bandage and fold it to the centre of its base, and then fold again. To make a narrow bandage fold the broad bandage again. If a collarbone be broken, place a thick pad under the armpit to act as a fulcrum. Sling the arm with the ordinary sling, but with the hand drawn up towards the far shoulder, and bind the elbow firmly to the side. *Pressure Points for Blood Stopping in Cases of Cut Arteries, &c.*—The blood systems are carried out by arteries and veins. The arteries, carrying a pulsating, crimson flow of blood direct from the heart, when cut spurt blood in pulsating gushes, as they

are forced by the action of the heart. The veins when cut give forth a steady, even flow of blood of a darker color than the arteries. They are bearing blood back to the heart, which pumps it through the lungs, to be refilled with oxygen and again forced through the arteries by the heart action. If an artery in the wrist is cut there would be a pulsating spurt of crimson blood that would carry perhaps a yard away. It would be practically useless to attempt to stop this flow by binding the forearm. The pressure point is just in the bend of the elbow. Take a small block of stone, wood, or whatever it may be, and wrap this in a handkerchief to avoid cutting the skin. Place the pad in the hollow of the elbow, and bind the wrist up to the shoulder, thus forcing the block hard against the artery, and stopping the flow. The same method applies to the upper arm, the pressure point being in the hollow under the arm. The pressure points of the body are 15 on either side, i.e., 30 in all. A small chart is the best from which to learn these. If a vein is cut, stop the blood flow on the side away from the heart. The flow is not nearly so strong, as the vein contains a series of valves that allow the blood through but stop it from falling back again. The best method when a vein is cut is to place a pad over the wound and bind tightly. If this does not stop the flow apply pressure on the vein just on the opposite side of the wound from the heart. In all serious cases of artery or vein cutting, broken bones, &c., the first-aid man's job is to apply what aid he can, and send for a doctor. If possible, do not leave the patient any longer than is necessary. *Common Forms of Wounds, Etc., Experienced on a Farm.*—A burn or scald is treated by first removing the clothing by cutting it off, and applying oil. Olive oil is in common use, and is very good. Then bind to keep away the air. Common cuts from which the blood oozes through capillary tubes from the blood vessels in the normal person will congeal in a short time. With snake bite it is necessary to stop the blood between the heart and the bite by a ligature, because the small capillary tubes carry poison. Then lacerate the wound through the two points where the teeth have marked it, about $\frac{1}{2}$ in. deep, and suck. Then rub into the wound a few grains of permanganate of potash—Condy's crystals. Insect stings, though not often dangerous, are seldom anything less than painful. A few drops of eucalyptus or ammonia on the bite will prove beneficial. Sunstroke is more or less common. Take the patient to a cool place, and strip to the waist. Raise the head and shoulders, and fan vigorously to supply a cooling draught of fresh air. Also apply anything cold—ice, water, or anything handy—to the head, neck, and spine. With

nearly all accidents treat for shock. Keep the patient quiet and warm. Give fresh air, but not a draught. Water or warm tea with milk is common as a stimulant." (Secretary, D. Jeff. Gordon.)

LENSWOOD AND FOREST RANGE (Annual average rainfall, 35in. to 36in.).

August 28th.—Attendance, 20.

DRAINAGE.—M. J. Vickers read a paper which dealt with all phases of draining orchard land. A number of questions were asked and a discussion took place on the cost of draining tiles which at present is considered excessive. He considered tile drains were the best in the long run because when properly installed they were trouble-free and would last indefinitely. He thought that apple growers were not fully aware of the importance of well drained land.

QUESTION BOX.—The meeting held on September 25 took the form of a Question Box and was attended by 14 members. The questions which had been submitted previously were dealt with by Messrs. H. Schultz and F. Rowley (sen.) who alternately answered a question, and was followed by the discussion of the meeting. The latest spray outfits operate up to 300 and 400lbs. pressure. Is this justified considering the extra wear and tear on engine, pump, hose, &c.? *Ans.*:—From 200 to 300lbs. pressure is ample to obtain a good and efficient spray. What is the best type of coulter for ploughing in a green crop in the orchard? *Ans.*: A disc coulter was preferred, although for burying green crop or rubbish a heavy disc plough was thought best. In view of the fact that approximately 120 tons of raspberries were grown in this district years ago and all sold, why is it that the few we grow now are not more easily disposed of? *Ans.*: Due perhaps to a number of reasons—(1) The sugar bounty making a prohibitive price for the housewife to buy sugar to make jam with. (2) The general depression. (3) Competition of Tasmanian pulp. (4) Negligence of certain growers who sell fruit in the market in improperly painted tins, which when emptied have a black appearance on the fruit. The highest grade of paint obtainable was not too good for protecting the tin from the acid of the fruit and the consequent dark color. Is this Branch of the Bureau doing enough to justify its existence? *Ans.*: Yes. The long time of its existence bears evidence of its justification. Also, being the means of disseminating valuable knowledge from time to time it is well justified. Is a winter oil spray payable, and if so would you apply one every year? *Ans.*: It pays the first year and perhaps the second, but not every year. Another member was of the opinion that a dressing of bone dust each year would do far more good than any amount of oil spray. What variety of pear is recommended for present planting? *Ans.*: Not advisable to plant any, but for general use Duchesse is as good as any. When is the best time to plant strawberries; autumn or spring? *Ans.*: If on clean ground, plant early in autumn and there will be a chance of getting a fair crop first year. If on dirty ground as late in the spring as possible.

At the meeting held on October 30 which was attended by 14 members and 11 visitors Dr. Jungfer gave an address on the subject, "Medical Progress in the Last 15 Years." He gave reports of doctors who inspected immigrant boats of the early settlers, and compared conditions with the present time. In those days there were no antiseptics, anaesthetics, vaccines, or knowledge of surgical cleanliness. A large percentage of cases of fever or smallpox were fatal. Due to ignorance of surgical cleanliness 8 cases out of 10 when operated on died of blood poisoning. There was much controversy over chloroform when first introduced, it being the belief that pain was natural to man and should be borne. Pasteur's work was described how by his researches he discovered how to control and prevent different germs. The system of pasteurization was thus named after him. The efficient work of the Quarantine Service was mentioned, it being said that little was heard of it because of its efficiency. With air services growing and the consequent rapid travel of passengers it was at present one of the problems of the Quarantine Authorities. Although much progress had been made, there was still much to be done, and the work of doctors in the future would be along lines of prevention, rather than treatment. (Secretary, B. Lawrence.)

MILANG (Average annual rainfall, 14.92in.).

August 5th.

CARE OF DAIRY PRODUCE.—Mr. J. Daniels read the following paper:—"The district in which we live is perhaps one of the most suitable dairying areas in the State; it has a suitable climate and rainfall, and natural feeding facilities. The first considera-

tion must be given to milking. Milk when first drawn is immediately affected by bacteria from the air, and may cause great harm if the hands and udders are not continually washed throughout milking. If these points are not adhered to the bacteria thrives and multiplies with alarming rapidity. Keep the separator and milking machine scrupulously clean. It is impossible to make a thorough job with a cloth and hot water; preferably use a good stiff brush. The use of a straining cloth tends to taint the milk. When cans are received from the factory scald before refilling, because the cans are washed and steamed in bore water, which is highly mineralised. Metallic taint is brought about by the use of bad and rusty cream cans caused by the tinned surface coming off the can. The chief defects in cream are:—Weedy, unclean, metallic, absorbed flavors, and fermenty, and are due to:—Unclean: Dirty methods on the farm, unwashed separators, buckets, &c. Weedy: Cows pastured on rape, lucerne, and dandelion at irregular intervals. Metallic: Using utensils that are not properly tinned and holding cream in kerosene tins. Absorbed flavors: To avoid this defect cool the cream, clean the dairy, and keep the cream away from odors. Fermenty: Mixing warm cream with cold. Cream under the Dairy Act is classified into three grades—choicest, first, and second. Choicest is a cream free from taints, of clean aroma, and suitable for making a first-class butter. First grade: Slightly tainted and slightly unclean. Second grade: Unclean, weedy, metallic, and fermenty. The points set out are:—Second grade, 36, 37, and 38 points; first grade, 39, 40, and 41 points; and choicest, 42 points and over. After the cream is taken delivery of it is weighed and entered into a weight book and sampled. After grading the cream is tipped into a sieve, and from there to a neutralising vat to which water is added, because the butter fat content is too high for churning purposes. A test is then taken to determine the amount of lactic acid in the cream. A sample (9c.c.) is put into a small dish, and a few drops of phenolphthalein indicator are dropped into the cream. A graduated burette containing a 1/10th solution of caustic soda is filled to the '0' mark, and then allowed to drip into the cream. When these reagents neutralise, the cream turns a faint pink. The dripping is stopped, and the reading taken to ascertain the per centage of acid in the cream. A chart is used to work out how much bicarbonate of soda is wanted to neutralise to a certain extent the acid that is in the cream. The whole of the acid is not neutralised, as this would affect the flavor of the butter. From this the cream is pasteurised. Pasteurising consists of heating the cream to 140° F. for at least 19 minutes, thus destroying bacterial life. Heating is followed by quick cooling to check spore formation. In the local factory the cream is heated to 190° to 200° F. Most food flavors are vaporised and pass off in steam, and most bacteria are destroyed. Care is taken not to scald the cream, and so avoid a cooked flavor. The cream is then subjected to rapid cooling, done by gravitating it over coils containing water first, and then brine at a temperature of 20° F., and finally ammonia expansion coils, and finally pumped into receiving vats to ripen. Heating and cooling takes less than a minute. After ripening the cream is churned at 45° F., the churn being previously cooled and scalded. The cream is churned until it changes into butter granules about the size of corn. The buttermilk is run off because its retention may leave mottles in the finished article. The butter is then washed in water at a temperature of 40° F. Two per cent. of salt is then added, and the butter finally worked to incorporate the salt and moisture." (Secretary, L. Yelland.)

WOMEN'S BRANCHES.

In the report of the Women's sessions of the 1933 Annual Congress, which appeared on page 349 of the October, 1933, issue, the following resolution was omitted:—"That where farmers come under the Farmers Relief Act, their wives and daughters who do work on the farm should receive under that Act portion of the crop for their own exclusive use, as a recognition of their labors and services to the community."

AUBURN (Average annual rainfall, 23.98in.).

October 27th.—Attendance, 24.

USES OF THE CITRON.—Mrs. C. Sandow, in the course of an address on this subject, said if the citron was better known housewives would use it in preference to orange for marmalade. She recommended the following recipes:—*Citron Peel*—Cut the citron into quarters, take out pulp, put into a jar with salt water—a handful of salt to 1 gall. of water; leave for three days, then put in fresh water for two days, changing each day, drain well. Boil in a large saucepan of water until tender enough to pierce with head of a pin, drain for 24 hours. Make a syrup by boiling for five minutes 1 pint of water to 1 lb. of sugar; place the peel in the syrup and boil quickly until a clear amber color or nearly all the syrup has disappeared. Take out the peel and sprinkle well with fine sugar and put in a dish to dry in a cool oven for an hour or so two or three days in succession, or dry in the sun. *Citron Ginger*—Cut citrons into eight or more pieces and take out pulp, boil for two hours and throw water away. Boil for two hours in fresh water, drain for 24 hours. Weigh, and to every 1 lb. of citron add 1½ lbs. of sugar and half pint water. Make a syrup of sugar and water; when boiling, add the citron and 2 ozs. of green ginger in a bag and 2 ozs. preserved ginger, cut in small pieces, to the pound. Boil until quite clear or when it jells—20 to 30 minutes. *Citron Conserve*—Treat citrons as for citron ginger, only use all the fruit and add 1 pint of water to every 1 lb. of citron and 1½ lbs. of sugar. Proceed as for citron ginger; this is done when clear, but the liquid does not set. *Sweet Citron Marmalade*—Boil citrons, drain, cut fine, and to every 1 lb. of fruit add 1½ lbs. of sugar and half pint water. Boil until clear. *Mixed Marmalade*.—To one small citron, allow two oranges and two lemons; weigh, cut up very fine, and to every 1 lb. of fruit allow 3 pints of water. Cover and leave overnight. Boil next day until tender, weigh, and to every 1 lb. of mixture put 1½ lbs. of sugar. Boil until it sets. Citrons must be ripe for all except the marmalade. (Secretary, Miss L. Dennison.)

BELALIE (Average annual rainfall, 17.71in.).

October 17th.—Attendance, 14.

JAM MAKING.—Paper contributed by Mrs. Fife.—“Fruit for jam making should be firm, sound, and just ripe—the fresher the better. If fruit is unripe the pectin or jellying power is absent. If overripe fruit is used, fermentation and moulds develop and the jam is wasted. Use a shallow, broad pan for preference, which allows the water to evaporate better than a deep preserving pan. Butter the bottom of the pan to prevent the jam from burning and avoid the need for skimming. Sugar acts as a preservative and for good results use only the best sugar. Most fruits require 1 lb. of sugar to each 1 lb. of fruit, the two exceptions being fig or melon, these requiring ½ lb. sugar to 1 lb. fruit, being deficient in acid. The addition of lemon juice or tartaric acid is needed to flavor—the quantity may be varied to suit individual tastes. Berry fruits do not need overnight preparation, but should be lightly bruised to start the juice flavoring. They require quick boiling to retain the color. The quicker jam is boiled after the sugar is added the better the result—about one hour is generally sufficient. Pears, apples, and quinces require steady, slow cooking to soften the fruit and long boiling if a rich color is desired after the addition of the sugar. Apricots and most varieties of plum should be halved, stoned, and covered overnight with half of the required amount of sugar. Moorpark Medium is a good jam apricot, Satsuma Plum a nice red table jam and Damson or Purple Gage Plums for jams, tarts or puddings. The addition of 1 lb. mulberries to 4 lbs. plums adds a distinctive flavor. Raspberries being poor in pectin are improved by the use of equal quantities of red currants and raspberries. Black cherries cooked half an hour before being added to gooseberry are an improvement, in the proportion of 3 lbs. cherries to 6 lbs. of gooseberries. Rounds of paper an inch larger than jars should be dipped in warm milk and when dry will be like parchment. I prefer jam bottled quite hot, pasted down, and left to cool before being stored in a dry, dark cupboard.”

RECIPES.—*Orange Jelly*—Slice six large Poorman oranges and two lemons thinly, add 6 pints water, stand all night, and then boil rapidly for one hour until it becomes pulpy. Strain through a jelly bag, measure liquid, and allow to every cup of juice

one cup of sugar. Boil for one hour until it jells, then skim well. *Preserved Figs*—6lbs. figs, three cups water, boil until soft, then add 6lbs. sugar, one teaspoon each of tartaric acid and ground cloves and $\frac{1}{2}$ lb. preserved ginger, sliced thinly. Boil three to four hours briskly, then bottle and seal. Will keep indefinitely. Use the small brown sugar fig and do not remove the stalk. *Peach Conserve*—6lbs. peaches, 6lbs. sugar, 1 cup cold water. Slice peaches to the thickness of $\frac{1}{4}$ in. and strew with all the sugar, add water, and allow to stand overnight. Bring quickly to the boil and cook until a rich wine color. The Elberta or other preserving peaches only are suitable for this delicious preserve, which must be sealed hot. *Quince Marmalade*—Cut quinces into dice and to every 1lb. of fruit allow 1 pint of water and 1lb. of sugar. Boil cores and peel separately in water and pour over sugar. Boil syrup 30 minutes, then add fruit and continue boiling until a deep rich red and the liquid jells when tested (Secretary, Mrs. A. Cummings.)

CLARE (Average annual rainfall, 24.53in.).

October 7th.—Attendance, 31.

BUTTER MAKING.—Paper read by Mrs. J. Miller:—"The making of butter is an historic art. It was as necessary to the health of the ancient Greeks as art was to their sense of the beautiful. It is hardly necessary to stress the fact that butter has a high vitamin content as well as food value, and that it is false economy to stint butter at the table, especially where growing children are concerned. Cleanliness is essential in all stages of butter production. The cows should be well housed besides being well and properly fed. Pasture-fed cows produce butter richer in vitamins than stall-fed animals do. Care must be taken to prevent butter being tainted by weeds or other unsuitable food. All dairy utensils must be kept properly clean with scalding water. A sunbath for separator and churn after being washed is an excellent germ killer. Scald wooden pats likewise. Separator cream should be cool before being mixed with other cream and must be kept cool. A home-made cool safe under a shady tree or in a draught is ideal for the summer. Cream should be made up into butter while fresh, allowing for weather conditions. If cream is kept cool it may be made up three times a week in summer and twice a week in winter. For quick and easy churning, the cream should be fairly thick. It should be worked until the buttermilk runs off the shiny surfaces of the solid mass of butter. Pour off the buttermilk and pour cold water over the butter, pressing and stirring the butter with a scalded wooden pat, and then strain off the milky water. This washing is repeated three or more times until the water pours off in a clear stream, and is very necessary, for if milky particles are left, the butter will be streaky and will not keep well. Press all the water out with the wooden pats, weigh, and allow about 1 tablespoon of salt and 1 teaspoon of sugar to each pound. The sugar counteracts the salt flavor and brings out the butter flavor better. It is a good plan to roll the salt so that it will mix evenly. Work the sugar and salt well into the butter. The butter is then weighed into pounds, patted into shape, and neatly covered with butter paper. Allow 1oz. over for shrinkage if the butter is to be kept." (Secretary, Mrs. W. McKendrick.)

COONAWARRA.

October 25th.—Attendance, 32.

PUDDING RECIPES.—*Twenty Minute Puddings* (Mrs. W. L. Redman)—Beat well 1 egg and 2 tablespoons sugar. Add 1 tablespoon melted butter, then $\frac{1}{2}$ cup milk and 1 cup flour, to which has been added 1 teaspoon cream tartar and $\frac{1}{2}$ teaspoon soda. Butter 5 cups, put currants, jam, rhubarb, or brown sugar at bottom. Pour in batter, cover with greased paper, and steam. Serve with sauce. *Carrot Pudding* (Mrs. O. Skinner)—4ozs. each butter or dripping, flour, and breadcrumbs, 1 teaspoon soda, 1 cup each grated carrots, sugar, currants, and milk. Mix all well together, pour into basin. Boil or steam $3\frac{1}{2}$ hours. *Cold Shape* (Miss O. Lear)—Dissolve $\frac{1}{2}$ oz. gelatine in cup hot water, let cool; beat in $\frac{1}{2}$ lb. sugar. Beat well the yolks of 2 or 3 eggs and add juice of 2 lemons; mix eggs and lemon juice in gelatine. Whip whites, add to mixture, and beat all together. Put aside to set. *Fruity Snow* (Mrs. O. Skinner)—Place alternate layers of "snow" and sliced mandarins (or any stewed or fresh fruit) with a sprinkle of cocoanut and chopped nuts in dish until full. Decorate top and serve cold. "Snow"—Boil 2 cups water and 1 cup sugar, add 2 tablespoons cornflour mixed with water, stir and cook 5 minutes. Add juice of 2 or 3 lemons (or any other flavoring), and when cool pour over stiffly beaten whites of 3 eggs. Beat until light. *Cocoanut Pudding* (Mrs. Lear)—One pint milk, 2 tablespoons each cornflour, sugar (crystals), 3 tablespoons cocoanut, 2 eggs, 2 tablespoons castor sugar, 1 tablespoon

butter, grated rind of lemon. Put milk and butter on to boil. Mix flour smoothly with a little of the cold milk. When milk boils, add flour and cook 2 minutes. Add cocoanut, lemon rind, and egg yolks well beaten with (crystals) sugar. Put in buttered piedish and stand in water in a moderate oven until set. Beat whites of eggs to stiff froth, stir in castor sugar lightly, spread on top of pudding. Put back in oven for a few minutes until set and a pale fawn color. *Sultana Baskets* (Mrs. Alder)—3ozs. sultanas, 1½ozs. butter, 2ozs. sugar, 2 tablespoons stewed apples, ½lb. short or flaky pastry, 2ozs. cake crumbs, 1oz. ground almonds, almond essence, 1 egg. Roll and cut pastry into rounds, line six deep tins; roll trimmings into a long, narrow strip, cut it into six pieces, twist, and form horseshoe of each; cream butter and sugar and well beaten egg; beat well and add other ingredients. Half fill each tart and bake 20 minutes in hot oven; take out handles after 10 minutes. Place handles upright on each tart to make basket. *Passion Fruit Pudding* (Mrs. Pounsett)—One cup sugar, 2 tablespoons flour, 2 eggs, 1 tablespoon butter, 4 passion fruits, 2 cups milk. Cream sugar and butter, add well beaten yolks, flour, milk, passion fruit pulp, and lastly stiffly beaten egg whites. Pour into piedish and place in large one containing hot water. Bake 1 hour in moderate oven and serve with boiled custard or cream. This sets with thick custard on bottom, a layer of passion fruit, and sponge on top. This mixture makes a nice lemon pudding, also if juice and grated rind of 2 lemons is substituted for passion fruit. *Boiled Puddings* (Mrs. Mitchell)—When possible, make puddings in a mould. Grease mould well and put butterpaper over top before putting on lid. A billycan makes a good mould. Steamed puddings are lighter than boiled because they do not come in contact with the water. The water should be boiling in which to put the pudding and kept boiling until the specified time for same to be served. Water should be replenished as it evaporates. There are many ways of preventing the mixture from sticking to the cloth, such as dipping cloth in boiling water, greasing or flouring it. Another plan is to line the cloth with grease proof paper. Always use good suet or butter; rancid fats will spoil a pudding. Plum pudding should not be served after a poultry dinner; a light dessert such as salads and jellies is preferable. When depended upon for their food value most boiled puddings have the necessary vitamins, but excessive cooking spoils all vitamins. Boiled puddings must have much cooking to turn out successfully. If it is desired to keep Christmas puddings for some time, dip in paraffin wax and hang in an airy place. Many boiled puddings can be prepared overnight, which saves time in the morning. *Sago Date Pudding*—One cup each breadcrumbs and dates or raisins, ½ cup sugar, 2 tablespoons sago soaked in cup of milk all night, ½ teaspoon carb. soda in a little milk, 2ozs. melted butter. Mix all ingredients, butter last. Steam in a greased mould for 2½ hours. *Marguerite Pudding*—2ozs. each dripping or butter and moist sugar, ½lb. S.R. flour, 1 egg, and a very little milk. Line mould with any kind of jam, or a layer of stewed fruit. Steam 1 hour. *Raisin and Orange Roll*—Crust: ½lb. flour, ½lb. suet, 2 teaspoons baking powder, water to make a medium dough. Filling: 2 cups seeded raisins, rind and juice of 2 oranges, golden syrup. Sift flour, baking powder, salt. Rub in shredded suet and add water. Roll out ½in. thick. Spread with syrup, cover with raisins and sprinkle with rind and juice of oranges. Put in floured cloth and boil 2½ hours. *Plum Pudding* (1)—½lb. each suet, moist sugar, raisins, sultanas, ½lb. each mixed peel and breadcrumbs, 4 eggs, 1 wine glass brandy, 2ozs. almonds, half nutmeg, and a little salt. Mix the beaten eggs and brandy together before adding other ingredients. Rub the flour and suet well together before adding fruit, &c. Boil 6 or 7 hours. *Plum Pudding* (2)—½lb. each sugar, raisins, currants, flour, butter, 4 eggs, 2ozs. lemon peel, half wine glass brandy, half teaspoon soda. Boil 7 hours. Beat butter and sugar, add eggs, then flour and fruits. *Meat Pies* (Mrs. Modistach)—½lb. to 1½lbs. beef or neck mutton, and 3 or 4 sheeps' kidneys. Put in layers with pepper and salt and cover each layer with flour. Fill up with cold water, cover, put in the oven, and cook slowly for 1½ hours. Cover with short crust, bake 15 to 20 minutes. If liked, onion and carrot can be added. Meat can be put through mincer instead of being cut, as is usually done. *Chicken or Rabbit Pie*—Take one medium sized or two young rabbits, bone, and cut up, stand in salt and water for 1½ to 2 hours. Arrange joints of rabbit in piedish with thin slices of ham or bacon and some yolks of hard boiled eggs. Cover with stock or water, add pepper and salt to taste and little nutmeg. Cover with puff paste. Bake 1½ hours. *Apple or Rhubarb Pie*—Stew apples with sugar, one or two cloves, and pinch of cinnamon, turn into piedish. Cover with puff pastry, or mix together 1 cup breadcrumbs, half cup sugar, 1 cup cocoanut. Moisten with a little apple or rhubarb juice. Put on top of fruit, whip the whites of two eggs, drop in spoonful on top, and bake until golden brown in moderate oven.

(Secretary, Mrs. F. Skinner.)

LAURA BAY.

September 5th.—Attendance, 8.

HOUSEHOLD HINTS.—Paper read by Mrs. D. F. Morrison:—"Store Hunt: When using silverfros for stoves pour off oil which is floating on top of mixture and add same quantity of kerosene, it will not turn brown with heat. When out of stove polish, mix equal parts of vinegar, boiled linseed oil, and kerosene. Shake until a creamy consistency. *To Remove Rust Stains* from fuji silk rub unsalted butter well into the silk and let lie about an hour, then wash in the usual way. *A Good Mop Oil*: 3 parts kerosene to 1 of raw linseed oil, put mixture in bottle and shake before using. *Tar on a Silk Dress or White Shoes* can be cleaned off easily by rubbing with eucalyptus. *To Remove Scorch Marks*: Make paste of magnesia and water, spread on part and when dry brush off powder. *To Remove Mildew from Linen*: Rub parts with soap and sprinkle with chalk, leave for a day then wash. Two treatments may be needed. *Carron Oil for Burns*: Mix equal quantities of olive oil and lime water. Keep closely corked, shake before using until thick and milky. *When Setting a Fowl*: Make hole in ground, pour in dipper of water, let soak in, then put straw and eggs; water and warmth from fowl steams egg shells and makes them easy to hatch. *To Clean Cloths or Rugs*: Mix sheep's or bullocks' gall with equal water, scrub until it becomes soapy and until it disappears and original color returns; put in fresh air to freshen. A few drops of Condy's crystals in water will keep fowls healthy. When making a quantity of sandwiches, put mustard in butter, add a few drops of hot water, and mix well; it is easier to spread and butter goes further; this is especially good in cold weather. *Bread Making*: A cup of cold water put in the oven when baking bread makes it steam and is much lighter and moist. A sprig of wormwood put in a cup of boiling water and a small quantity of solution taken twice a day will cure boils. *Cough Mixture*: 3d. worth each of peppermint, paregoric, laudanum, and aniseed, pour 1 pint boiling water on 1lb. treacle, stir when cool, add above mixture, bottle and cork well." (Secretary, Mrs. D. Morrison.)

McLAREN FLAT.

November 2nd.—Attendance, 20.

MANUFACTURE OF BUTTERMILK POWDER.—The Hon. Secretary (Mrs. D. Elliott) presented the following paper:—"Buttermilk is generally used for feeding pigs, and most of the large manufacturers dispose of their buttermilk for that purpose. The buttermilk is run from churns into tinned steel holding vats. If the milk contains but little acid, it is often left overnight in order that acid to the proper degree may develop. The milk is then gravitated to the drying plant. This consists of two oblong steel rollers placed together and revolving at a speed of 20 revolutions per minute in opposite directions. The rollers are hollow and steam under pressure is used for heating same. Steel knives are affixed at correct angle on the roller for removal of the solids. A hood, leading through the roof of the building, is generally made of galvanized iron and is placed above the rollers in order to cope with the evaporated moisture. The live steam inside the rollers is, by the means of a pressure pump, returned to the steam boiler. The operation commences by the rollers being gradually heated and set in motion. The blades are then adjusted to the rollers. When the rollers have the required heat, buttermilk is run into the distributors above the roller, from there an even flow of milk is led over the hot rollers. There the milk starts boiling, the moisture evaporates, and the solids adhere to the rollers. The solids consist of casein, sugar, and fat. The latter in very small quantities, generally about 5 per cent. In order to recover the thin film of milk solids, sharp knives are forced on the bright polished surface of the rollers and sheets of solids resembling paper are seen leaving the roller. If the knives are blunt or the rollers too hot the solids are burnt and discolored, whereas with milk of proper acidity, with knives in good condition and carefully adjusted, the steam pressure correct, a product almost white and quite palatable is obtained. The sheets of solid milk are worked through a medium fine sieve into bags. The powder has a flaky, velvety appearance. It mixes well with other ingredients, crushed grain, &c., which, in proper balanced proportions, forms the latest idea in feeding chickens and fowls."

MILLICENT (Average annual rainfall, 29.76in.).

November 17th.—Attendance, 7.

SALAD RECIPES.—*Japanese Salad*: 2 lettuces, 1 apple, 1 large orange, 3 or 4 radishes, $\frac{1}{2}$ tin small sliced pineapple, $\frac{1}{2}$ lb. ripe tomatoes. Wash the lettuces, drain and arrange leaves in a circle in salad bowl. Cut orange sections in halves, peel the tomatoes and

apple, cut up fruit into small cubes, slice radishes thinly. Mix fruit with salad dressing. *Cream Dressing*: 2 tablespoons thick cream, $\frac{1}{2}$ tablespoon Worcester sauce, pinch castor sugar, 1 dessertspoon lemon juice, salt and pepper. Mix cream gradually with sauce, sugar, salt, and pepper; stir in lemon juice by degrees. *Cooked Salad Dressing*: 1 teaspoon mustard, 1 dessertspoon butter, 1 tablespoon sugar, 1 egg, 1 gill milk, 3 table-spoons vinegar, $\frac{1}{2}$ teaspoon salt. Mix butter, mustard, salt and sugar; break egg on to it and beat 1 minute, then add milk and vinegar. Cook until it thickens and resembles custard, stirring all the time. If put in an airtight vessel this will keep. *Fruit Salad*: 2 slices pineapple, 3 bananas, 1 orange, $\frac{1}{2}$ lemon, few strawberries, 1 apple, 1 tablespoon pineapple juice or light wine, $\frac{1}{2}$ pint whipped cream, castor sugar, 3 passion fruit. Pare and core apple and cut into small dice, also pineapple. Peel and cut bananas into rings. Peel orange, remove pith, and cut into small pieces. Put fruit in layers in small dish, sprinkling with lemon juice and sugar. Pour juice or wine over. Decorate with whipped cream and strawberries. *Cucumber, Onion, and Tomato Salad*: Scald 2 large tomatoes, peel and slice, adding 2 teaspoons of sugar. On a separate dish peel and grate cucumber, adding a teaspoon of salt. On the third dish peel and cut very finely an onion, then cover it with vinegar. Soak for an hour or two. Strain salt water from cucumber, add tomatoes and onion just as they have been soaking. *Lettuce Salad*: Wash and shred 2 heads of lettuce. Boil 2 eggs hard. Remove shells and mash the yolks fine. Mix well together the juice of 1 or 2 lemons, 2 or 3 tablespoons water, 1 dessertspoon of sugar, $\frac{1}{2}$ tablespoon of salt, 1 tablespoon sweet cream, adding this last to prevent curdling, and the yolks of the eggs, and pour over the lettuce. Cut the whites of the eggs into rings and arrange on top. *Beetroot Salad*: Boil beetroot until tender. Rub peel off and slice. Boil a level teaspoon of cloves and a piece of cinnamon bark in a cupful of vinegar with a dessertspoon of sugar added, pour over beet and then put a cupful of the liquid, in which the beet was boiled, with the beet. *Salad Dressing*: $1\frac{1}{2}$ tablespoons vinegar, 1 teaspoon mixed mustard, 1 tablespoon sugar, $\frac{1}{2}$ teaspoon salt, $\frac{1}{2}$ tablespoon butter. Yolk of raw egg. Mix above ingredients into raw paste and hold over a fire until very thick, stirring well all the time. When cold thin with milk. *Veal Brawn and Salad*: 1lb. veal, 1 part stock, $\frac{1}{2}$ lb. of bacon or ham, 2 hard-boiled eggs, 1 teaspoon chopped parsley, salt and pepper, 1oz. gelatine, $\frac{1}{2}$ teaspoon grated lemon rind. Rinse a mould with cold water and decorate with some of the eggs and bacon. Cut up veal, bacon and eggs into neat dice. Fill mould with neat layer of these, season each layer. Dissolve gelatine in stock and pour over meat. Place a greased paper over top and cook in moderate oven 2 to 3 hours. Fill up with rest of stock when cooked; when cold turn out and garnish with shredded lettuce, sliced tomato, diced carrot, cold peas, sliced cucumber, and beetroot. (Secretary, Mrs. M. Hutcheson.)

MUNDALLA (Average annual rainfall, 19.22in.).

October 27th.—Attendance, 15.

BISCUIT COMPETITION.—The Branch conducted a successful Biscuit Making Competition. The Misses D. Carson and M. Knowing were awarded first and second prizes respectively for the best six varieties made from one economical recipe. The following are the winning recipes:—*Mixture, Cream Biscuits*.—Beat 1 cup sugar and 1 cup butter to a cream. Add 1 cup sweet cream, then 4 cups plain flour and 1 teaspoon cream tartar, half teaspoon soda. (1) Roll out thin and bake in moderate oven. (2) *Cocoanut Biscuits*.—Take piece of mixture and add cocoanut. (3) *Mushroom Biscuits*.—Roll out piece mixture, cut into rounds, and bake. When cold, ice bottom with chocolate icing and when dry ice top with white icing (mix with white of egg). Make remainder of icing very stiff and mould into shape of stems. (4) *Almond Fingers*.—Roll out dough very thin. Spread with icing sugar mixed with white of egg. Sprinkle with chopped almonds, cut in fingers, and bake light brown. (5) *Raspberry Fingers*.—Roll out piece of mixture and spread with raspberry jam. Have ready 1 egg, half cup sugar, and 1 cup cocoanut mixed together. Sprinkle on top of jam and bake a light brown. (6) *Fairy Rings*.—Roll out piece of mixture, cut in rings, half having smaller ring cut from centre. Bake, and when cold fill with jam and ice with lemon icing.

Drying Woollen Caravans, &c.—Draw old silk stockings through sleeves and peg stockings to line. Articles retain shape and dry quickly.

Ants.—Paint edges of doors and shelves with carbolic acid.

Questions.—Should bread tins be washed after every baking? *Ans.*: As bread takes longer to rise in fresh tins, most people only wash after every other baking. Which is the correct way to season poultry? *Ans.*: Parsley for fowls, sage for ducks, thyme

for mutton. Use an egg to bind ingredients, and if cut up onion is placed in basin with pinch of soda and boiling water over it, seasoning does not repeat. Which is correct way to place pastry in Napoleon cake? *Ans.*: Put the pastry top and bottom, sponge in centre. What will create an appetite? *Ans.*: Place pinch hops in tumbler of boiling water. Take before meals. (Secretary, Miss M. Kemp.)

WARCOWIE (Average annual rainfall, 11.42in.).

October 31st.—Attendance, 14.

INFANT NURSING.—Mrs. G. Hilder read the following paper:—"The following methods gained from personal experience have proved beneficial to both mother and baby. From the time the baby leaves the hospital regular hours for bathing, sleeping, and feeding are essential. This promotes regular habits and lightens the burden of the daily routine of the mother where the housework is concerned. Let the baby commence the day by having the first feed about 6 a.m., and after changing the clothes allow him to lie in the cot until about 8.30 a.m., which is bath time. After doing this, if the baby is at all constipated, a teaspoonful of orange juice every morning is advisable. Child should be ready for a second feed about 9 a.m. Providing the baby is properly bathed and fed he should sleep until the next feed about 12 noon, and care must be taken to see that the child has as much fresh air and sunshine as possible. The baby's next feeding time is about 3 p.m., and then towards evening time, about 5.30 p.m., give another bath and feed and put him to bed. The last feed, of course, for the night should be about 10 p.m. After this final feed, change him, put him in a warm, dry bed, so made that he cannot kick off the clothes. He should sleep until morning without stirring. Sometimes it is necessary to give a drink of water between feeds. This method of baby caring is good until the child is up to six months old, and then a change of diet can be made by feeding on arrowroot biscuits soaked in boiling water to which has been added a little sugar. When cutting the teeth, it will be found of considerable assistance if the baby is allowed to bite on bones and crusts. A healthy baby should commence to crawl at 10 months and walk at 12 months. Remember that for a healthy, happy baby and a contented mother regularity, plenty of fresh air and good food and exercise are essential." (Secretary, Mrs. Crossman.)

WASLEYS.

October 4th.

The meeting took the form of a flower show, the adjudicators being Mr. and Mrs. F. Gilbert, of Roseworthy College, who awarded the prizes as follows:—Twelve cut flowers—Miss E. Fagg, first; Mrs. J. Hancock, second. Six cut flowers—Miss E. Fagg, first; Mrs. W. C. Toll, second. Six roses—Mrs. Sanders, first. Table decorations—Miss E. Fagg, first; Mrs. E. Day, second. Posies—Mrs. W. C. Toll, first; Mrs. J. Hancock, second. Shoulder sprays—Miss G. George, first and second. (Secretary, Miss J. Braun.)

DRESSMAKING.

Paper read by Miss R. Heffernan at the October Meeting of the Kybybolite Branch.]

In dressmaking there are many things to be taken into consideration, the chief of which are:—(1) How to take measurements; (2) How to draft a pattern; (3) placing and cutting patterns. (a) In cutting—(1) Allowing fullness; (2) flares, &c.

TAKING MEASUREMENTS.

Not knowing how to take measurements correctly often results in wasting good material. Again, should one send away for a frock ready made, the exact measurements should be given to ensure a good fit.

The person to be measured must stand erect. Tie a piece of tape around the waist and pull gently into position to make a waist line, for a number of measurements are taken either to or from that line.

Neck.—The neck measurement is taken firmly, but not tightly, around neck, midway between base of neck and chin.

Bust.—This is taken loosely with the tape measure well up over the shoulder blades at back and around over the fullest part of the bust.

Across Chest.—Take this in line, 2in. below the base of the neck, from where the arm joins the body at one side across to the other.

Across Back.—Is taken in line with and 4in. below the nape of the neck from where the arm joins the body at one side across to the other.

Bust Rule.—Some people would think that by halving the bust measurement the back and front patterns should naturally fit. That is not so. A separate measurement is needed for the bust because it is necessary to allow for the fullness in front and the side seam towards the back. Therefore, this bust rule is necessary. Take half across the back plus 1in. and subtract from half bust measurement.

Under Arm.—From well into the armpit to waist line. There is a standard shoulder measurement. For adult 5in., for a child 3in.

Sleeve.—Three measurements are necessary:—(1) Full length; (2) around top; (3) around elbow. Full length is taken with arm outstretched from well into the armpit to the bone at the wrist. Around top of sleeve is taken with the arm hanging to the side around top of armhole over the point of the shoulder blade. To be done tightly. Around elbow is taken firmly, but not tightly, with the arm well bent and taken well over the point.

Skirt.—(1) Waist is taken tightly around the waist line. (2) Hips in line with and 6in. below the waist line loosely around the hips.

These are the most essential measurements. There are others of minor importance that are easily taken, such as front length, back length, ordinary length, &c.

Miss Heffernan here demonstrated the drafting of a pattern.

PLACING AND CUTTING PATTERNS.

In placing patterns, place centre front straight down fold of material. On velvet, place all patterns the same way—with the pile running from bottom upwards—so that the pile will fall out and show the full depth of color. All other cloths with a nap or sheen must run from top downwards.

After placing patterns, always allow ½in. for seams all round. After finished cutting out the pattern and it is desired to make it about 1in. wider, allow 1in. down the centre front by moving it back from the fold the required distance. If it is allowed around the outside of the pattern it will spoil the shape and cut of the frock.

To allow fullness in front by tucks or gathers, split up the pattern and spread it apart about 3in. Then place on the material, cut out, and make two or three small rows of gathering or about four ½in. tucks. The same applies to children's clothes. One can make a little yolk and cut open the bottom in four places—two in front and two at the back and allow 2in. or so for smocking or pleats or gathers.

For flared coat, skirt, or flared frills, it is necessary to cut out a foundation pattern. Draw a line from top to bottom every 2in. or 3in. apart. Cut up a flare. Frills are done in a similar manner.

HINTS ON MACHINE.

Heavy Running of Machine may be Caused by.—(1) Being clogged by fibres of material, dust, &c.; (2) being choked by bad oil; (3) not having been oiled regularly; (4) various oil holes being overlooked; (5) the driving belt too tight or too loose.

The Breaking of Upper Threading may be Caused by.—(1) The upper tension being too tight; (2) by machine being wrongly tested; (3) the needle being too fine for material or cotton; (4) the needle being set too low; (5) the needle being blunt; (6) the eye not being sufficiently polished, leaving sharp edges which will cut the thread as it passes through; (7) Another make of needle being used that does not suit the machine; (8) the shuttle worn roughly or sharply in places through lack of oil.

The Breaking of Shuttle Thread may be Caused by.—(1) The shuttle tension being screwed in too tightly or shuttle incorrectly threaded; (2) the hole in stitch plate becoming rough or jagged through a badly set needle touching it occasionally; (3) the shuttle becoming worn by constant use.

Irregular Stitches may be Caused by.—(1) Too thick a material being used for needle; (2) the shuttle thread being thicker than upper thread; (3) the upper tension too tight or slack; (4) the tension of shuttle too tight or too loose.

Missed Stitches may be Caused by.—(1) The needle being set too high; (2) the needle being set too low; (3) the needle being too blunt; (4) the needle being bent; (5) the needle being too fine for thread.

Stitches Puckering may be Caused by.—(1) Too long a stitch; (2) top tension too tight; (3) machine threaded incorrectly.

A FEW USEFUL HINTS.

When binding flares, collars, &c., cut the binding as narrow as possible and on the true cross, otherwise it will not set correctly.

An easy way of finding out how much material is required to make a pleated skirt with 2in. pleats is to take three times the hip measurement.

Do not have iron over hot for pressing silk. Heat causes silk to cut.

One way of finishing off a garment is to nick small V-shaped pieces out along the edges of seams; it will prevent it from fraying.

A Few Suitable Styles and Colors to suit Different People.—A stout person should never wear trimmings or bright stripes running around the figure; have them running straight up and down. For a tall, thin person, trimming running round is most suitable.

Suitable Colors.—The blonde with blue eyes, reddish, yellow hair, and pink cheeks has the easiest task in choosing becoming colors. Violet and blue to tone with her eyes; pink, grey, black, and white would become this type. The girl with auburn hair would look well in deep plum, dark blues, dark green, and also brown that would tone with her hair. The lady with grey hair, who wishes to look much younger, must wear a dark toning under her chin and grey to match her hair. Black and white would look well on this type. A very important point about color is that a color that suits in daylight will often dishearten under gaslight.

To Remove Shine.—Steaming is resorted to to remove shine and restore material to its natural appearance. Place a damp cloth over the shine marks, press with a hot iron for a few seconds until steam is raised, then remove damper and slap the part affected with open hand. Brush well and all shiny patches should disappear. Another way is place damp cloth on pressing table and lay shined material on this. Place dry cloth on the wrong side and press with moderately hot iron. This draws steam from damp cloth. Velvet or jersey velour may be restored by steaming over a basin of boiling water.

How to Prevent Colors from Running and Fading.—To set blue, brown, and brownish red shades, soak material for two hours in a solution made of 1oz. of sugar of lead to every gallon of water. Take care to dissolve carefully before placing garment or material in solution. This process will set the above colors permanently. To set green, mauve, purple, or purplish red shades, soak material in alum water, using 1oz. of alum to 1gall. of water. A simple method that may prevent colors from running when washed is to add about 1oz. of salt to 1gall. of water and rinse material in this after washing.

SALADS.

[Paper presented by Mesdames Quirk and Victorson at the November meeting of the Clare Branch.]

Attendance, 35.

Salads are wholesome, appetising, and easily made, and this with their small cost renders it possible to have them daily in hot weather. There is nothing so refreshing after a hard day's work in the hot sun to find that the evening meal consists largely of fresh, cool vegetables prepared in such a way that they make an instant appeal to the most jaded appetite. This is particularly so at harvest time. At this period there is little spare time for the housewife to prepare meals that need a lot of preparation and there is such variety that can be had with easily obtained ingredients when dealing with salads that they make the exacting work of providing attractive summer meals comparatively easy.

Nearly all fresh vegetables can be used in salads. In America they associate in their raw state carrots, cabbage, turnip, and many other vegetables not generally in use with us as a main ingredient of a salad.

Lettuce is the foundation of many appealing salads and is the vegetable mostly used in this country, but many others when cooked can be used for making up dishes that when treated with a dressing are refreshing and nourishing. It is generally recognised that the iron and other minerals contained in vegetables purify the blood and act as a tonic to the system. Any cold meat, fish, or poultry left over from a previous meal may be cut into small thin pieces and mixed with salad vegetables.

Three main things are necessary in salad making:—(1) The vegetables must be fresh and young; (2) they must be dried after washing; (3) the salad dressing must not be poured over them until just before serving. (4) Oil or cream is absolutely necessary in order that a salad shall not be indigestible.

RECIPES.

Potato Salad.—Boil the required amount of potatoes in their jackets—use potatoes that do not break easily—until nearly cooked; small new potatoes are best. Peel while hot and cut in slices, and while hot add about one teaspoon of olive oil, pepper, and

salt, cut an onion up finely, a little sugar, and moisten with white vinegar. If preferred, mayonnaise dressing can be used instead of the above ingredients. Garnish with parsley.

Bean Salad.—Cut French beans either across or lengthways and boil until tender. Drain off liquid and add an onion, cut up finely, salt, pepper, and a little sugar, and moisten with vinegar.

Celery Root Salad.—Put the celery roots on to boil until tender, then drain liquid and cut in slices, add pepper, salt, and vinegar.

Salad from left over Cooked Vegetables.—A little lettuce, onion, French or haricot beans, peas, or pieces of celery chopped finely; add salad dressing.

Beetroot Salad.—Boil a bunch of beetroot until quite soft, then cut in thin slices. Place in salad bowl and between each layer of beetroot put some white pieces of uncooked celery and a few drops of vinegar. Sprinkle with a little pepper and salt and stand for a few minutes. *Dressing.*—Put 1 oz. of butter in a saucepan; when melted add one tablespoon of flour; mix well, then add one cup of milk, and stir until it boils. Put it aside to cool. Boil an egg hard. Mix a little mustard, pepper, salt, and sugar in a cup, add the yolk of the hard-boiled egg and blend all with just a little drop of milk; add this to the dressing, mix well, and pour over the beetroot. Garnish with the white of the egg and a few pieces of beetroot.

Cucumber Salad.—Cut up cucumber very fine and sprinkle with pepper and salt. Make a dressing of cream, vinegar, a little sugar, and pour over the cucumber.

Tomato Salad.—Cut up tomatoes, cucumber, and onion very fine, sprinkle sugar, pepper, and salt on it, add vinegar. Mint or parsley chopped up very fine makes an improvement to this salad.

Orange Salad.—Oranges peeled and cut in small pieces, sprinkled with sugar one hour before using, are delicious. Add cream or custard, cocoanut.

Peaches, peeled and prepared the same way, are also delicious.

Bananas in stewed fruits are an improvement. Cut the bananas up about half an hour before serving.

DRESSINGS.

(1) Hard boiled eggs, pepper, salt, sugar, mustard, cream, and vinegar must be used the same day.

(2) Put 3 eggs in a jug, add 1 small cup sugar, 1 cup milk, 2 teaspoons mustard, 1 teaspoon salt, 1½ cups vinegar. Stand in a saucepan of water and boil until dressing thickens. Bottle and cork. This will keep for about two months. If onion is disagreeable to the taste and to get the flavor into a salad, rub out the bowl with onion before putting in salad.

To make a lettuce crisp, put a steel knife in the water with the lettuce. Lemon used instead of vinegar in salads is less harmful for most people.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

Lower North, at Riverton, Thursday, February 22nd, O. E. Longbottom (Secretary).

Yorke Peninsula, at Port Victoria (Wauralte Branch), Wednesday, March 7th, M. Newbold (Secretary).

South-East (Upper), at Wolseley, Wednesday, March 21st, E. W. Sharraff (Secretary).

South-East (Lower), at Tantanoola, Wednesday, April 11th, H. M. Kennedy (Secretary).

Dairying, at Milang, Wednesday, May 9th, L. E. Yelland (Secretary).

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Warning to Users of Sodium Chlorate.

The Director of Chemistry (Mr. W. T. Rowe) has drawn attention to the danger inherent in the use of sodium chlorate as a weed destroyer. He has made a special request that as a warning to users of this compound the following report received from the New Zealand Department of Internal Affairs on Explosives and Dangerous Goods for the year ended March 31st, 1933, should be published in this *Journal*:—

"It is desired to call attention to the dangers incidental to the handling of sodium chlorate, a compound which is finding extensive application in the farming industry for spraying noxious weeds. The chlorate is rich in oxygen and renders any organic matter with which it comes in contact highly inflammable—for instance, clothing impregnated with it will ignite readily from a spark or flame.

"A typical accident attended with fatal results occurred during the year. The victim had been spraying 'ragwort' and his clothing had become well saturated with chlorate solution and had subsequently dried out. Whilst smoking a cigarette at lunch-time, a glowing ember fell on his clothes, which burst into fierce flames.

"A further danger lies in the fact that sodium chlorate, when intimately mixed with organic matter, forms a powerful explosive which is extremely sensitive to friction and percussion, and which, under ordinary conditions of handling, is liable to explode prematurely. It is understood that at farmers' meetings such mixtures have been described as 'cheap and simple explosives' for farm use. Several accidents—at least one with serious consequences—have been recorded during the year, the mixture used being sodium chlorate and sugar. Explosives formed from such mixtures are not authorized for use in New Zealand, and the Department has issued a warning that the mixing of sodium chlorate with other materials to form explosives is illegal, and that a prosecution will be taken against any person found engaging in the practice. Irrespective of any injury which may be incurred those concerned in the matter of this class of explosive are liable to a heavy monetary penalty."

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

Dundee Wheat.

Asking for information concerning Dundee wheat, a variety that has rapidly increased in popularity in New South Wales, a subscriber to the *Journal of Agriculture* has been advised that Dundee has proved to be far superior to Federation in yield, grain quality, and disease resistance. Local baking tests have already indicated the improved quality of Dundee, and this has been corroborated by Dr. Kent Jones, England, who states that Dundee is a decided improvement in general strength (*i.e.*, baking quality) over even good commercial Australian wheat. Dundee is destined to make considerable headway in cultivation in New South Wales, and perhaps also in other States. With the development of wheats of such grain quality, the British miller will find that Australian wheat will show improvement in general strength and he will be able to use it more freely in his blend.

Baking tests have been made also with promising new wheats. Broadly speaking, these tests have shown that Dundee, Ford, and Canimbla are superior in baking quality to the present popular varieties.

The Principal of Roseworthy Agricultural College (Dr. A. R. Callaghan) says that the Pelschenke time figure of several wheats tested at the College last year was:—Florence, 86; Dundee, 68; Ford, 56; Sultan, 56; Waratah, 41; Sword, 33; Nabawa, 33; Gallipoli, 27. At the University of Sydney last year the time figure for Dundee was 120 and for Ford 70.

The sample harvested at Roseworthy Agricultural College this season is of excellent appearance, plump, hard, and heavy, and it is expected to show a very high time figure when tested out.

TOP SPECIAL SUPER (45%)

Crop with "TOP"—Its "SUPER."

The Adelaide Chemical & Fertilizer Co., Ltd.

Analysis of Chinese Cabbage.

The Department of Agriculture has had analysed a sample of Chinese cabbage for a poultry keeper at Hindmarsh. The sample of Chinese cabbage has shown up very well, and on the figures recorded should prove a first-class foodstuff for poultry. In comparison with other well-known greenfeeds it is really nutritious and being such a soft, sappy plant should be readily digestible.

Composition.

	Moisture.	Crude Protein.	Fat.	Nitrogen-free Extracts.	Fibre.	Ash.	Starch Equivalent.	Nutrient Ratio.
	%	%	%	%	%	%	%	
Chinese cabbage .	80.0	5.2	0.8	6.9	2.2	4.9	8.4	1 to 2.0
Mustard	80.0	4.0	0.6	9.4	4.0	2.0	9.6	1 to 3.4
Mangels	80.0	1.9	0.2	14.4	1.6	1.9	10.5	1 to 11.0
Lucerne	80.0	4.0	0.6	7.9	5.5	2.0	8.0	1 to 2.5
Rye	80.0	2.4	0.6	9.2	6.6	1.2	10.0	1 to 6.7

The very narrow nutrient ratio of 1 to 2.0 and the high content of ash (4.9) means that provided the Chinese cabbage does not prove to be excessively laxative, it should be a first-class greenfeed for poultry, and particularly for growing chicks and laying hens.

Deterioration of Seed Wheat.

The Secretary of the Sutherlands Branch asked: "Is it possible that, even though seed wheat is annually graded, a variety may deteriorate with loss of prolificacy?"

Reply—Careful grading of seed wheat keeps up the prolificacy of seed wheat because, other things being equal, large seeds give higher yields than small seeds, and also produce a larger proportion of large seeds than are secured from small seeds. On the other hand, grading does very little towards keeping a variety true-to-type and, as a matter of fact, may lead to its more rapid deterioration in this respect. If a variety of wheat contains as an admixture another variety of large grain, grading tends to increase the proportion of strangers, because the machine retains the larger grains. The only sure way of keeping a variety of wheat true-to-type and fully vigorous is to grow a small plot in wide-spaced rows, remove all strangers by hand, and carefully and regularly grade all seed sown. If an attempt is to be made to improve a variety of wheat, it is necessary to go a step further and hand select all heads from which the grain is to be secured to plant the small plot in wide-spaced rows.

Feeding Wheat to Sheep versus Marketing Grain.

A correspondent from Streaky Bay, in seeking advice as to the advantages of feeding wheat to sheep rather than marketing of the grain, mentions that the price for wheat at the local siding is 2s. per bushel, less 5d. dockage, for a sample below f.a.q.

Reply—The isolation of the districts which comprise Central Eyre's Peninsula and the lack of suitable markets for animal products other than wool, make the selling of wheat other than as grain a very difficult proposition. Under present conditions, even though wool prices are good and wheat prices very low, it does not appear that wheat can be economically converted into wool. With sheep averaging 12½lbs. of wool, of which 97 per cent. realised 16½d. per lb, and wheat weighing 57lbs. per bushel, only bringing 1s. 7d. per bushel at the railway, it might appear on the surface that more money would be received for the wheat if it was converted into wool instead of carting it to the railway siding, but a close investigation of the matter rather dispels this idea.

On the assumption that the number of sheep carried on the farm can be doubled if they receive wheat at the rate of 1lb. per head per day, the following calculations can be made:—If there are 400 sheep now on the farm, 800 can be carried if fed 1lb. of wheat per day. The 4,867bush. of wheat required for a year's feeding is worth at 1s. 7d. per bushel, £385 6s. 1d.

A GEAR-LIKE GRIP that keeps you **SAFE !**

DUNLOP

Gold Seal

The deep Helical pattern of the Dunlop tread grips the road like one helical gear grips another---and grips its full width. Go in a hurry---and, from shoulder to shoulder, Dunlop bites into the road --- transmitting the maximum engine power. Stop in a hurry---and the same wider road-grip makes your brakes more effective --- holds you back from danger. Drive on wet or greasy surfaces---and Dunlop safely holds the road. Fit this great Australian tyre for safety, more mileage, silence and economy. Today's prices are lower than ever before --- and your local dealer stocks all sizes.

HELICAL TREAD PATTERN

The Dunlop tread pattern is based on the principle of helical gearing---one of the most efficient methods of transmitting power. By adapting it to a tread pattern Dunlop solved the problem of how to give tyres the maximum traction. This helical tread is one of Dunlop's most important improvements in tyre construction.

The Dunlop tyre is a product of Dunlop Perdreau Rubber Co. Ltd.---the largest manufacturing organisation in Australia, employing 5000 Australian workers and making every variety of high-class rubber goods.

The extra 400 sheep will cut, at 12½lbs. per head, 4,933½lbs. of wool, which at 16d. per lb. would be worth £328 17s. 9d.

The feeding of 1lb. of wheat per sheep per day might more than double the sheep-carrying capacity of a holding in Central Eyre's Peninsula, but taken year in and year out, the probabilities are that the increase will not be very much more than doubling the number, and if this is so wheat as cheap as 1s. 7d. per bushel cannot be economically converted into wool.

Feeding Value of Oat Varieties.

Goolwa asks: "Can you supply me with figures showing the feeding values as gram and hay of Algerian, Early Burt, Mulga, New Zealand Cape, Palestine, and Lachlan Oats?"

Reply—We have no figures showing the feeding value of Palestine oats, but the following figures, which are the averages of two separate years, should provide what you require:—

Oats as Hay.

	Algerian.	Early Burt.	Lachlan.	Mulga.	N.Z. Cape.
	%	%	%	%	%
Moisture	10.0	10.0	10.0	10.0	10.0
Ash	5.5	5.6	5.4	6.1	5.8
Crude protein	4.6	4.4	4.5	5.4	5.2
Fat	2.6	3.3	2.3	2.7	2.4
Nitrogen-free extracts . .	51.0	49.1	51.9	50.4	50.0
Fibre	26.3	27.6	25.9	25.4	26.6
Digestible protein	3.2	3.0	3.2	3.7	3.6
Digestible fat	1.7	2.1	1.5	1.8	1.6
Digestible carbohydrates . .	29.4	28.4	29.9	29.1	28.9
Digestible fibre	14.5	15.2	14.2	14.0	14.7
Starch equivalent	34.9	34.4	34.9	35.3	34.6
Nutrient ratio	1 to 14.9	1 to 16.1	1 to 14.8	1 to 12.7	1 to 13.1

Oats as Grain.

Moisture	8.0	8.0	8.0	8.0
Ash	3.6	3.6	3.2	3.2
Crude protein	10.0	8.8	9.6	10.3
Fat	5.1	7.4	4.7	5.7
Nitrogen-free extracts . .	60.2	60.7	62.9	61.8
Fibre	13.1	11.5	12.4	11.8
Digestible protein	7.2	6.5	6.6	7.0
Digestible fat	3.9	5.8	3.6	4.4
Digestible carbohydrates . .	43.2	43.9	45.5	44.6
Digestible fibre	3.1	2.7	2.9	2.8
Starch equivalent	58.3	61.8	59.1	60.1
Nutrient ratio	1 to 7.6	1 to 9.1	1 to 8.5	1 to 8.2

The summary of these figures, shown as starch equivalent and nutrient ratio, disclose that as hay there is very little difference between any of the five varieties of oats from a fattening point of view, but because of the narrower nutrient ratios Mulga and New Zealand Cape oats are better than the others for the production of milk and for promoting growth with young animals. The analysis of the samples of grain show Early Burt to have the highest starch equivalent and so is the best fattening variety, whilst Algerian is the poorest for this purpose, but on the other hand, New Zealand Cape and Algerian are better than the others for milk-producing animals and growing youngsters.

Barley for Pigs.

Alberton asks: "What is the best method of feeding barley to pigs?"

Reply—It is generally recognised that the best way to feed barley to pigs is after crushing, but it is not always economic to go to the expense of grinding the grain. The relative values of various treatments of barley for pig feeding are somewhat as follows:—About 4lbs. ground barley to produce 1lb. live weight in pigs, and about 4½lbs. soaked barley and about 5lbs. dry whole barley for similar results. Barley should never be cooked for pigs; as a matter of fact, the only ordinary pig foodstuff that is improved by cooking is potatoes.

Tested and Proved

for

every Power Kerosene job

Proved by tests in laboratory and on the farm to be knock-proof — and therefore able to release the maximum power your engine was designed and built to give. No matter what the job may be VOCO Power means **FULL POWER** and being knock-proof you get flexibility . . . No knocks when you suddenly load the engine, only a full powered pickup—smooth and swift. Use VOCO, its outstanding quality means more work from less fuel.

VACUUM OIL COMPANY PTY. LTD.

MALLEE FARM COSTING—FARM No. 1.

(Continued from page 648).

[By ARTHUR J. PERKINS, Director of Agriculture.]

PART III.—STUDY OF MALLEE FARMING COSTS.

A.—COSTS OF GROWING WHEAT PRECEDED BY BARE FALLOW.

1. *Introductory.*

It is fairly obvious that the average farmer, and in particular the average Mallee farmer, has neither the time nor the training to keep accounts that permit of accurate determination of the mean costs of the various operations in which he might be engaged. Indeed, the utmost that could perhaps be expected from average farm accounts would be that they should show the extent to which total farm receipts less inclusive farm expenditure would suffice for the upkeep of the farmer and his family, after meeting current farm expenditure of the same season, that is to say, whether or not what has come to be known as the Farmers' Management and Labor Income would be likely to prove adequate.

Nevertheless, accurate Costing Accounts involving detailed analysis of costs in all farming operations, have both individual and general or "political" values. To the individual farmer, working under conditions approximating fairly closely to those obtaining on the farm or farms on which mean costs have been determined, their value should be two-fold; on the one hand they should constitute a guiding standard in the matter of probable costs of production in his farming operations; and on the other, they should indicate in what direction personal economies are possible in any particular operation. It should not be forgotten, however, that "costing" accounts are only indirectly related to profits; the latter, other things being equal, are essentially controlled by seasonal conditions and current market prices. It follows that the main object of the successful farmer has always been to reduce costs of production per acre to a minimum, without impairing normal farming efficiency, whilst leaving costs per bushel to the arbitrament of cosmic and economic factors.

The general or "political" values of Costing Accounts usually relate to district, State, or even Continental questions, and would be dependent for their cogency upon the extent to which the mean data availed of painted a sufficiently accurate picture of the area of country to which they were supposed to correspond. Nor should it be forgotten that just as on one and the same farm, "costs" per unit of production, as distinct from "costs" per unit of area, vary within very wide limits from season to season, so both costs per unit of area and particularly costs per unit of production, may vary considerably from district to district in one and the same season, under the stimulus of Economic, Seasonal, or Soil variations characterising the several districts. Hence, although we are often asked to express an opinion on the matter, it is not possible to state with any degree of accuracy what are the mean costs of production of wheat per acre, or per bushel in South Australia, and still less in the Commonwealth, without taking into consideration the mean costs in all well defined wheatgrowing districts, duly weighted proportionately to the areas harvested in each district. Unfortunately, no such mean data are available, nor are they likely to be until such time as official notice be taken of a presidential address delivered by me before the Australasian Association for the Advancement of Science in 1928.* In the meanwhile, we must perforce remain satisfied with such partial instalments towards a completed scheme as the one at present under review: it is to be hoped, too, that in the course of time farmers in other districts will submit their accounts for detailed analysis over periods of not less than three years.

* *Vide Journal of Agriculture*, January, 1928, page 590: "A Plan for National Research into the Economic Position of our various Rural Industries."

2. *General Costs of Growing Wheat on Mallee Farm No. 1 contrasted with corresponding Turretfield 1922-32 Means.*

Detailed Costing Accounts were kept on the Turretfield Demonstration Farm over a period of 10 successive seasons. It should be recalled that the latter farm is situated in the Central Statistical Division of the State, and consists in the main of heavy soil, offering special tillage difficulties. It follows that working conditions on this farm are very different from those of an average Mallee Farm, and in particular of Mallee Farm No. 1.

Summarised wheat costs for the two types of farms are shown below:—

<i>Mallee Farm No. 1.</i>				
	Areas Sown.	Mean Yields	Mean Costs.	
	Acres.	per Acre.	Per Acre.	Per Bush.
		Bush.	£ s. d.	s. d.
Season 1929-30	448	14.35	2 13 6	3 9
Season 1930-31	339	16.87	2 9 9	2 11
Season 1931-32	479	19.35	2 3 4	2 3
Means 1929-32—	422	16.92	2 8 8	2 11

Turretfield Demonstration Farm.

Means 1922-32—	309	19.49	4 10 8	4 8
--------------------------	-----	-------	--------	-----

As might have been anticipated, the costs of growing wheat on the lighter and cheaper Mallee country, both per acre and per bushel, are appreciably lower than corresponding Turretfield costs, namely, 46.32 and 38.36 per cent. respectively. These variations in costs will receive detailed consideration at a later stage in this report.

3. *Detailed Costs of Growing Wheat on Mallee Farm No. 1: Means of Seasons 1929-30, 1930-31, and 1931-32.*

Full details of mean costs of growing wheat on Mallee Farm No. 1 have been given in Table VII. (Parts I., II., and III.) in the Appendix; this Table consists of three parts, namely:—

Part I.—In which the mean yearly total expenditure incurred during three successive seasons of wheat growing have been given in detail for a mean area of 422 acres and a mean yield per acre of 16.92 bushels; individual costs have also been expressed as percentages of total costs.

Part II.—In which items of Part I. have been expressed as Costs per Acre.

Part III.—In which items of Part I. have been expressed as Costs per Bushel.

Part I. of Table VII. shows Total Mean Expenditure of growing 422 acres of Wheat yielding 16.92 Bushels per Acre, to have been £1,026 17s. 3d. per annum. The items of Expenditure incurred admit of grouping together in order of importance as follows:—

	Costs.			Percentages.
	£	s.	d.	%
1. Use of motive power (horses and tractor)	294	7	5	28.66
2. Miscellaneous (interest, taxes, &c.)	243	11	8	23.72
3. Materials (seed, super, bags, &c.)	235	4	7	22.91
4. Labor (direct only) and contracts	167	2	8	16.28
5. Use of implements	86	10	11	8.43
	£1,026	17	3	100.00

From the above it will be noted that on a Tractor Farm, of the five groups of items summarised, the use of motive power is the most costly.

For purposes of comparison corresponding Turretfield groups, representing the means of 10 successive seasons—1922-32—have been contrasted on a per acre basis.

	Mallee Farm No. 1. 1929-32—16.92Bush.			Turretfield Farm. 1922-32—19.49Bush.		
	Costs per Acre.		Percent- ages.	Costs per Acre.		Percent- ages.
	s.	d.	%	s.	d.	%
Use of motive power	13	11	28.7	19	1	21.1
Miscellaneous	11	7	23.7	27	9	30.6
Materials	11	2	22.9	20	1	22.1
Labor (direct only) and contracts	7	11	16.3	16	9	18.5
Use of implements	4	1	8.4	7	0	7.7
Totals	48	8	100.0	90	8	100.0

From the above it will be observed that Costs per Acre of a 19½ bush. crop at Turretfield—90s. 8d. per acre—were considerably greater—over 86 per cent.—than corresponding costs of a 16.92 acre crop on Mallee Farm No. 1; and also that the proportional relationship of the five Expenditure groups was not the same on the two Farms. Thus, on the Mallee Farm the most costly group was the use of “motive power”—namely, 28.7 per cent. of total costs—whilst at Turretfield it was “Miscellaneous,” which included Interest, &c.—namely, 30.6 per cent. But, apart altogether from the inherent differences between the two farms, it is necessary to stress the fact that the results of Mallee Farm No. 1 are the means of the 1929-32 period, and those of Turretfield of the 1922-32 decade; and that during the first seven seasons of the latter decade costs of production were appreciably greater than in the three closing years of the decade, which actually correspond to the three seasons with which the data of Mallee Farm No. 1 are concerned. In the circumstances a fairer comparison would, therefore, be obtained if the data collected for each farm had reference to the same period of years, namely, 1929-32; and accordingly the data that follow below will help to establish this comparison:—

	Mallee Farm No. 1. 1929-32 Mean Costs.			Turretfield Farm. 1929-32 Mean Costs.		
	Per Acre.	Per Bush.	Percentage	Per Acre.	Per Bush.	Percentage
	s.	d.	%	s.	d.	%
Wages (direct) and contracts	7	11	16.3	13	6	17.0
Use of Horses (and Tractor)	13	11	28.7	16	4	20.6
Use of Implements	4	1	8.4	5	2	6.5
Seed	3	2	6.4	6	9	8.5
Superphosphate	4	2	8.5	5	4	6.7
Bags and Twine	3	10	7.9	4	9	6.0
Rates and Taxes	0	5	0.8	1	4	1.7
Interest on working Capital	3	7	7.4	6	9	8.5
Interest on Land and Improvements	5	6	11.3	15	9	19.8
Balance of Expenditure	2	1	4.3	3	9	4.7
Totals	48	8	100.0	79	5	100.0

Mean Yields per Acre 16.92 Bushels.

19.20 Bushels.

The above statement shows that notwithstanding relative parity in economic conditions it cost 30s. 9d., or 63 per cent., per acre more, and 1s. 2d., or 40 per cent., per bushel more, to grow wheat at Turretfield than on Mallee Farm No. 1. The main increases per acre may be summarised under the following heads:—

	£	s.	d.
Interest on land and improvements	0	10	3
Labor	0	5	7
Interest on working capital	0	3	2
Horses and tractor	0	2	5
Implements	0	1	1
Rates and taxes	0	0	11
Total	£1	3	5

These differences are partly due to the heavy character of the Turretfield soil, which renders tillage operations more costly than in the Mallee; partly because of more difficult labor conditions on a Government managed farm; and partly because of very much higher land values. From the general point of view the comparison may be taken to show very definitely that in existing economic conditions wheat can be grown far more cheaply in the Mallee than in the Central and Lower North Divisions, notwithstanding the higher mean yields per acre of the latter.

In the statement immediately preceding the one we have just had under consideration it was shown that on a tractor farm, motive power was the most costly of five groups of items of expenditure. It must be stressed here, however, that as Interest was shown in the aggregate under Miscellaneous, those groups concerned in Interest were not debited with their interest quotas; hence they show up to greater advantage than they otherwise should. Interest quotas have been added to the groups concerned, with the following results:—

	£	s.	d.	Percentages. %
1. Motive power	318	10	7	31.02
2. Materials	241	13	4	23.53
3. Miscellaneous	184	12	6	17.98
4. Labor and contracts	167	2	8	16.28
5. Implements	114	18	2	11.19
Totals	£1,026	17	3	100.00

It will be observed that if interest be taken into consideration, the cost of Motive Power on a Mallee Tractor Farm would be 31.02 per cent. instead of 28.7 per cent. of total expenditure as previously indicated.

4. *Summarised Statements of Mean Costs of Growing Wheat on Bare Fallow on a Mallee Farm in comparison with corresponding Turretfield Data.*

Finally, mean costs of growing a 16.92bush. crop of wheat sown on Bare Fallow of Mallee Farm No. 1 have been summarised under Statements "A," "B," and "C" in comparison with corresponding data of 10 successive seasons at Turretfield.

STATEMENT "A".

From the standpoint of Seasonal Field Operations.

	Mallee Farm No. 1. Mean Costs (1929-32).				Turretfield. Mean Costs (1922-32).

Totals	2	8	8	100.0	4	10	8	100.0

STATEMENT "C".

From the standpoint of Interest and Depreciation.

Depreciation on Improvements and Plant	0 10 7	0 8	21-8	0 8 7	0 5	9-5
Interest on Land and Improvements	0 5 6	0 4	11-3	0 15 11	0 10	17-6
Interest on Floating Capital	0 3 0	0 2	6-2	0 6 0	0 4	6-6
Interest on Overdraft ...	0 0 7	—	1-2	0 1 1	0 1	1-2
Interest and Depreciation Charges	0 19 8	1 2	40-5	1 11 7	1 8	34-9
Balance of Expenditure .	1 9 0	1 9	59-5	2 19 1	3 0	65-1
Totals	2 8 8	2 11	100-0	4 10 8	4 8	100-0
*Labor (direct)	0 7 6	0 6	—	0 16 9	0 10	—
Labor (indirect)	0 1 8	0 1	—	0 5 6	0 4	—
	0 9 2	0 7	—	1 2 3	1 2	—

We may note in the first place that over a period of three consecutive seasons the mean costs of growing a 16.92 bushel crop of wheat on a Mallee Farm were respectively £2 8s. 8d. per acre and 2s. 11d. per bushel; on the other hand corresponding **10 year means on the Turretfield Demonstration Farm** were £4 10s. 8d. and 4s. 8d. respectively.

In the latter connection attention may be drawn to the fact that on the Turretfield Farm interest charges were at the rate of 23s. per acre and 1s. 3d. per bushel, whereas on the Mallee Farm corresponding charges were 9s. 1d. and 6d. respectively; that is to say at Turretfield increases in interest charges above corresponding Mallee Farm No. 1 charges were 153 per cent. and 150 per cent. respectively. These facts will help to explain why wheat can be grown at less cost in the Mallee than in Central or Lower North districts.

But, it has already been stated that during the three seasons that the Mallee Farm accounts were under observation there was a general reduction in costs of production throughout the State relatively to corresponding costs incurred in the Turretfield 10-year period. A fairer comparison of costs would, therefore, be costs incurred in the same period of three years in either case; and such a comparison is given below:—

STATEMENT "A".

From the standpoint of Seasonal Operations.

1929-32 Seasons.

	Mallee Farm No. 1, 16-92 Bush.			Turretfield, 19-20 Bush.		
	Mean Costs.			Mean Costs.

Balance of Expenditure .	1	9	0	1	9	59-5	2	8	6	2	6	61-0
Totals	2	8	8	2	11	100-0	3	19	5	4	1	100-0
*Labor (direct)	0	7	6	0	6	—	0	13	6	0	9	—
Labor (indirect)	0	1	8	0	1	—	0	5	3	0	3	—
	0	9	2	0	7	—	0	18	9	1	0	—

Hence, we see that during the 1929-32 three season period the cost of growing a 19.20 bushel crop at Turretfield was reduced to £3 19s. 5d. per acre, and 4s. 1d. per bushel, as compared with £4 16s., and 4s. 11d. for the 7-year period closing on June 30th, 1929, on the same farm, and £2 8s. 8d. and 2s. 11d. on Mallee Farm No. 1. The increases above corresponding data of Mallee Farm No. 1 were £1 10s. 9d., or 63 per cent., and 1s. 2d., or 40 per cent. respectively.

Differences in Interest charges, on the other hand, remained approximately similar, namely, 13s. 8d. per acre, or an increase of 150.4 per cent., and 8d. per bushel, or an increase of 133.3 per cent.

In the matter of increases other than Interest increases the Turretfield figures were 17s. 1d. per acre, or 43 per cent., and 6d. per bushel, or 21 per cent. In other words, if Interest charges had been the same at Turretfield as on Mallee Farm No. 1, the Turretfield costs per bushel of wheat would have been 3s. 5d. only instead of 4s. 1d.

Another reason for Turretfield increased costs was greater tillage difficulties of heavy clay soils. The preparation of the Turretfield Fallows cost 18s. per acre against 12s. 1d. on Mallee Farm No. 1. Costs of Harvest Operations, on the other hand, were actually lower on a per bushel basis at Turretfield than on Mallee Farm No. 1, and only 6d. higher on a per acre basis.

5. Costs of Delivering Wheat at Country Sidings.

Figures hitherto given concerning the "costs" of growing wheat have referred to "costs" actually incurred on the farm itself; but the farmer's costs do not end with the sewing up of his bags; he still has to deliver the wheat to the nearest Railway siding. At Turretfield these costs of delivery averaged out at 2½d. per bushel; Mallee Farm No. 1, which is only two to three miles from a railway station, is more conveniently situated for the purpose. In each of the three seasons the wheat was delivered at the railway siding under contract, and with the following results:—

Seasons.	Wheat Carted. Bushels.	Costs of Delivery.	
		Total. £ s. d.	Per Bushel. d.
1929-30	5,450.62	21 15 0	0.96
1930-31	5,882.37	26 3 4	1.07
1931-32	8,040.50	25 0 0	0.75
Means	6,461.16	24 6 1	0.90

Hence, the mean "costs" of delivering wheat to the railway siding have been nine-tenths of a penny per bushel, and the inclusive cost of growing and delivering the wheat at the nearest siding 3s. per bushel. Clearly, however, the "costs"

would be proportionally greater for farms of the same district less conveniently situated for wheat marketing purposes. If, in addition, railway freight be taken into consideration, inclusive costs would be represented by 3s. 6d. per bushel, on trucks, Port Adelaide.

Wheat reserved for Seed and Feed purposes was also carted under special contract to the Farm Barn with the following results:—

Seasons.	Wheat Carted. Bushels.	Cost of Contract Carting. Total.			Per Bushel. d.
		£	s.	d.	
1929-30	806	1	13	2	0.49
1930-31	665	1	8	4	0.51
1931-32	48	0	5	0	1.25
Means	506	1	2	2	0.53

In addition to the above, in 1931-32 season 1,180 bushels of wheat were carted to the Farm Barn by the Farm's teams at a total cost of £5 4s. 11d., or 1.07d. per bushel. Hence, during the three seasons the cost of delivering wheat from the harvest field to the farm barn has been at the mean rate of $\frac{3}{4}$ d. per bushel.

6. *The Extent to which Wheat Costing Data of Mallee Farm No. 1 can be extended to the Murray Mallee District generally.*

In the immediately preceding paragraphs it has been shown that in the three successive seasons by no means above average, the mean costs of growing a 17bush. wheat crop on a Mallee Farm, were represented by 2s. 11d. per bushel on the Farm, 3s. at the railway siding, and 3s. 6d. on trucks Port Adelaide. For purposes of comparison "Costs" incurred in each individual season have been summarised below as follows:—

	Areas Reaped. Acres.	Mean Yields Per Acre. Bush.	Total.			Cost of Production. Per Acre.			Per Bush.	
			£	s.	d.	£	s.	d.	s.	d.
1929-30	448	14.35	1,198	19	11	2	13	6	3	8 $\frac{1}{2}$
1930-31	339	16.87	843	6	10	2	9	9	2	11 $\frac{1}{2}$
1931-32	479	19.35	1,038	5	0	2	3	4	2	3
Means	422	16.92	1,026	17	3	2	8	8	2	10 $\frac{1}{2}$

It will be observed that under stress of economic conditions, the owner succeeded in reducing mean "Costs of Production Per Acre" from £2 13s. 6d. in 1929-30 to £2 3s. 4d. in 1931-32; this represents reduction in "Costs Per Acre" of close on 20 per cent. in spite of progressively improving yields, and is, therefore, a notable performance.

But whilst the above data show what can be done by careful management and good farming methods on a Mallee Farm, it would be unwise to assume that they can be applied indiscriminately to all Mallee Farms in general. Indeed it is perhaps necessary to recall at this stage that however low and satisfactory these mean costs of production might appear to be, the owner's Management and Labor Incomes had negative values in two out of the three seasons, namely—£539 0s. 9d. in 1929-30, and—£639 10s. 1d. in 1930-31; and again a negative value for the mean of the three seasons, namely—£249 9s. 8d. It is scarcely necessary to add that these negative Management and Labor Incomes were not the consequences of managerial shortcomings, but in the main of the unprecedented fall in world prices of primary products, and to a less degree of unfavorable seasons.

But whilst these data can be taken to illustrate fairly well what can be done in the Mallee, they must not be assumed to be typical of what is happening to-day on the average Mallee Farm. The most glaring instance of dissimilarity between

this Farm and Mallee Farms generally is the fact that during these three years all wheat grown on Mallee Farm No. 1 was sown on well tilled bare fallow; and the costs that have been indicated are for wheat so grown. It is true that departmentally we recommend that over the greater portion of South Australia wheat should not be grown in any other manner, and particularly not in the Mallee; nevertheless, for a variety of reasons it is not yet the generally accepted conception as to how wheat should be grown in the Mallee. Hence, in County Chandos, in which Mallee Farm No. 1 is situated, we find that during the five-year period ending in 1932, out of a mean total area of 187,923 acres sown to wheat, 58,188 acres, or 31 per cent. of the total, had not been fallowed prior to seeding; and that whilst the mean yield per acre of the area that had been fallowed was 11.05 bushels, that of the land that had not been fallowed was 5.14 bushels only.

Obviously the Economics of Wheat sown on stubbles, grass land, or new land must be quite different from those of wheat sown on adequately tilled Bare Fallow; and equally dangerous would it be to generalise as to prospects in County Chandos on the basis of Wheat Costs of 2s. 11d. per bushel.

Moreover, the mean yield per acre of land treated as Bare Fallow in County Chandos, namely, 11.05 bushels, is not the mean yield per acre of Mallee Farm No. 1, namely, 16.92 bushels; and if we assume—as we may—that “costs per acre” of growing wheat on bare fallow in County Chandos generally will be approximately similar to corresponding costs on Mallee Farm No. 1, then we shall find that the lower yield per acre of the County as a whole will imply considerably higher “costs per bushel” than have been recorded for Mallee Farm No. 1. What should be the exact value of these mean County Costs per bushel it would be very difficult to state without further investigations; but if we assume “costs per acre” to remain the same as on Mallee Farm No. 1, apart from costs of harvest operations which should vary proportionally to mean yields per acre, we shall get the following results:—

	Mean 1929-32 Costs per Acre of Mallee Farm No. 1.	Estimated Mean Costs per Acre of Wheat Sown on Bare Fallow in County Chandos.
	£ s. d.	£ s. d.
Preparation of fallows	0 12 1.24	0 12 1.24.
Seeding operations	0 11 3.01	0 11 3.01
Harvest operations	0 11 1.84	0 7 3.41
Balance of expenditure	0 14 1.91	0 14 1.91
Total mean costs per acre ..	2 8 8.00	2 4 9.57
Mean yields per acre	16.92bush.	11.05bush.
Mean costs per bushel	2s. 11d.	4s. 0½d.

(*Vide* Table VII.—Part I. of Appendix.)

Hence, if we assume that apart from varying harvesting costs, “costs per acre” of growing wheat on Bare Fallow in County Chandos to be approximately similar to corresponding “costs” of Mallee Farm No. 1, then after due allowance for variation in harvest costs, the mean costs per bushel would be approximately 4s., or about 1s. more than corresponding costs of Mallee Farm No. 1.

But if we go further afield and extend our comparisons to the seven counties of the Murray Mallee Statistical Division, we shall meet with even greater dissimilarities. In these counties for the five-year period ending in 1932, the mean area under Wheat in each year was 933,592 acres, of which 530,761 acres, or 57 per cent. had not been fallowed prior to seeding; the mean yield per acre of wheat sown on fallowed land was 7.97 bushels and that of wheat sown on land that had not been fallowed 4.28 bushels only.

Obviously, therefore, the mean costs of growing wheat on nearly three-fifths of the area sown to wheat in the Murray Mallee Division must differ radically from costs recorded for Mallee Farm No. 1; on the other hand, costs per acre on the remaining two-fifths of the area sown which would have been fallowed prior to seeding, would approximate to corresponding costs of Mallee Farm No. 1, subject to due allowance for variation in harvest costs. The latter costs have been summarised below:—

	Mean 1929-32 Costs per Acre of Mallee Farm No. 1.	Estimated Mean Costs per Acre of Wheat Sown on Bare Fallow in Murray Mallee Statistical Division.
	£ s. d.	£ s. d.
Preparation of fallows	0 12 1.24	0 12 1.24
Seeding operations	0 11 3.01	0 11 3.01
Harvest operations	0 11 1.84	0 5 3.04
Balance of expenditure	0 14 1.91	0 14 1.91
Total mean costs per acre	2 8 8.00	2 2 9.20
Mean yields per acre	16.92bush.	7.97bush.
Mean costs per bushel	2s. 11d.	5s. 4½d.

From the above it will be observed that whereas the mean costs of growing a 17bush. crop on Mallee Farm No. 1 were £2 8s. 8d. per acre and 2s. 11d. per bushel respectively, it was calculated that the average Mallee Crop of 8 bushels to the acre should cost about £2 2s. 9d. per acre and 5s. 4½d. per bushel respectively.

Such an estimate of Mean Costs for Mallee Farms will at first sight seem high; but it may be justified on the following grounds. It can be stated in the first place that if we take into consideration all interest and depreciation charges it is difficult to imagine that land could be adequately prepared for wheat over nine successive months, appropriately sown to wheat and dressed with superphosphate, and that eventually the crop should be reaped and bagged for less than £2 per acre; and for a mean crop of 8 bushels, £2 per acre means 5s. per bushel. Moreover, 8 bushels per acre represents the average wheat yield of land treated as bare fallow in the Murray Mallee Division; and it follows that in the same division there must be many farmers, who sow wheat on bare fallow, and reap less than 8 bushels to the acre, and whose costs per bushel would, therefore, be greater than 5s. The Government Statist's data for 1931-32—a by no means unfavorable season—show that out of 2,367 farmers in the Murray Mallee Division, 1,011 or over 42 per cent., reaped less than 6 bushels to the acre. It is true that many of the latter—possibly the majority—sowed their wheat crops on stubble, grass, or new land; but a fair proportion must have sown their wheat on bare fallow; and if we make allowance for probable slovenly and defective treatment, and reduce the mean costs of the latter to 30s. per acre, 5 bushels per acre would still represent mean costs of 6s. per bushel, and lower yields proportionally more.

In summary, it can be said that in the absence of violent economic upheavals, and apart from harvest variations, mean costs per acre will usually remain fairly constant in any given district for a definite period of years, say 5 to 10; whereas costs per bushel, on the other hand, must necessarily vary with every rise or fall in mean yields of grain per acre, and the latter would, in the main, be controlled by seasonal conditions and the incidence of disease. Hence, whilst we can probably safely accept the mean costs per acre of Mallee Farm No. 1 for growing wheat on bare fallow, namely, £2 8s. 8d., as applicable to Mallee Farms generally, the same cannot be said of the mean yield per acre, namely, 17 bushels, and the mean costs per bushel, namely, 2s. 11d., which two items are in reality typical of no

more than 3 per cent. to 4 per cent. of present day farmers in the Murray Mallee Division. In the circumstances, it can be said that mean costs per bushel of growing wheat in the Mallee are nearer 5s. than 3s.

7. Comparison of Mean Costs of Growing Wheat on Mallee Farm No. 1 and at Turretfield respectively, in Seasons in which Mean Costs Per Bushel were approximately similar.

From the comparisons that have already been made, it is fairly obvious that the cheaper and more easily worked Mallee Lands can grow wheat at lower costs than the dearer and heavier lands of the Central and Northern Areas. It remains to be seen to what limits Central and Northern Mean Yields per acre must be raised in order to approximate Mallee Mean Costs per bushel. In the records of the 10 Turretfield seasons there was one season in which "costs per bushel" approached very closely to corresponding "costs" for 1929-30 season on Mallee Farm No. 1. I refer to 1924-25, when Turretfield crops averaging 23.91 bushels per acre cost 3s. 10d. per bushel to grow; similarly, on Mallee Farm No. 1 the mean crop yield for 1929-30 was 14.35 bushels, and the mean cost per bushel 3s. 9d.

For purposes of comparison these mean data have been summarised under Statements "A," "B," and "C" respectively:—

Contrasting Mean Costs of Growing 23.91bush. of Wheat at Turretfield with corresponding Costs of Growing 14.35bush. on Mallee Farm No. 1.

To all intents and purposes we have here the costs per bushel of a 14bush. Mallee Crop contrasted with corresponding costs of a 24bush. Central District Crop, and notwithstanding a difference in mean yields of 10 bushels between the two, these mean costs were practically identical, namely, 3s. 9d. and 3s. 10d. per bushel respectively; in fact, if we make allowance for the fact that costs of production in 1924-25 were higher than in 1929-30, the 1d. which separates the two mean costs would be more than accounted for. If we assume mean costs per bushel to be identical in each case, namely, 3s. 9d., then the costs per acre of the 14bush. Mallee Crop would be £2 12s. 6d., and that of the 24bush. Central Division crop £4 10s. We may conclude, therefore, that whilst in Mallee Areas mean yields of grain per acre are usually lower than in our Central and Northern Areas, this disadvantage is usually set off by lower land values and less costly tillage operations, with the result that on parity of yields, inclusive costs per bushel are very appreciably lower in the Mallee than in the Central and Northern Areas. The data given above show that whereas in the Mallee Areas 3s. 9d. per bushel for wheat on the farm would balance expenditure on a 14bush. crop, a similar position could not be expected in the Central and Northern Divisions except from crops yielding from 9 to 10 bushels more than the Mallee Crops.

If from the latter standpoint we take one of the best of our Lower North Counties—Stanley—on the one hand, and one of the best Mallee Counties—Chandos—on the other, and compare their respective mean yields of wheat per acre for the most recently recorded decade, namely, 1922-32, we shall find 15½ bushels for Stanley and 10½ bushels for Chandos, that is to say, a difference of 5 bushels per acre only. Hence, it follows that in times when the mean price of wheat is low, Mallee farmers are probably in a sounder economic position than farmers in the older settled districts.

8. *Financial Aspects of Delayed Fallowing in the Growing of Wheat.*

In March, 1929, an area of 79 acres was sown to a grazing crop of oats: this crop was grazed over throughout the season and not broken up for wheat until December of the same year; the land so treated was subsequently sown to wheat in the 1930-31 season. We have here an example of what might be called unduly delayed fallowing, a practice which is not usually recommended for Mallee Districts, because of its usually depressing influence on wheat yields. In the paragraphs that follow we shall examine some of the financial implications of late fallow in comparison with normal early fallow.

It must be stated here that the 79 acres broken up late in December yielded 827 bushels of wheat, or 10.47 bushels per acre, whereas 339 acres of normal early fallow yielded 5,720 bushels, or 16.87 bushels per acre, an increase above late fallow of about 6½ bushels per acre, or 61.1 per cent.

Summarised comparative costs per acre have been given below:—

The costs per acre can now be expressed comparatively as costs per bushel as follows:—

	Mean Costs per Acre.		Late Fallow Decreases.	
	Late Fallow.	Normal Fallow.	Total.	Percentage.
	£ s. d.	£ s. d.	s. d.	%
Tillage of fallows	0 8 5	0 12 6	4 1	32.7
Seeding operations	0 11 5	0 11 7	0 2	1.4
Harvest operations	0 8 7	0 11 4	2 9	24.3
Balance of expenditure ..	0 10 7	0 14 4	3 9	26.1
Totals	1 19 0	2 9 9	10 9	21.6
Mean yields per acre .	10.47bush.	16.87bush.		

Hence the "costs per acre" of the crop sown on late fallow were 10s. 9d., or 21.6 per cent. less than the corresponding costs of the crop sown on early fallow; this represents an aggregate saving of £42 9s. 3d. on the 79 acres sown.

The saving of 4s. 1d. per acre, or 32.7 per cent., on normal costs of fallowing is attributable to reduction in number of tillage operations given. The costs per acre of seeding operations were, as might have been anticipated, to all intents and purposes identical. There was a reduction of 2s. 9d. per acre on harvest operations, attributable to the reduction in mean yields per acre. The balance of expenditure showed a reduction of 3s. 9d. per acre, or 26.1 per cent., which can be distributed under the following headings:—

	Balance of Expenditure.		Late Fallow Decreases.	
	Late Fallow.	Normal Fallow.		
	s. d.	s. d.	s. d.	s. d.
General Expenses	4 2	5 3	1 1	
Rates and taxes	0 4	0 6	0 2	
Interest	6 1	8 7	2 6	
Totals	10 7	14 4	3 9	

The costs per acre can now be expressed comparatively as costs per bushel as follows:—

	Mean Costs per Bushel.		Late Fallow Increases.	
	Late Fallow.	Normal Fallow.	Total.	Percentage.
	s. d.	s. d.	d.	%
Tillage of fallows	0 9.68	0 8.91	0.77	8.6
Seeding operations	1 1.06	0 8.26	4.80	58.1
Harvest operations	0 9.81	0 8.05	1.76	21.9
Balance of expenditure .. .	1 0.15	0 10.16	1.99	19.6
Totals	3 8.70	2 11.38	9.32	26.3
Mean yields per acre ..	10.47bush.	16.87bush.		

Hence, although a 10.47 bushel crop of wheat sown on late fallow cost 10s. 9d. per acre less to grow than a 16.87 bushel crop sown on early fallow, on a per bushel basis the wheat sown on late fallow cost 9.32d. per bushel more to grow than the wheat sown on early fallow; or, in other words, if wheat had realised on the Farm 2s. 11½d., receipts would have balanced expenditure for wheat sown on early fallow, but would have left wheat sown on late fallow at a debit of 9.32d. per bushel, or in the aggregate of £32 2s. 4d. for the 79 acres. It is suggested, therefore, that notwithstanding the advantage of a few more weeks' grazing, late fallowing for wheat is rarely economically profitable in average Mallee Districts, and particularly so in these days of low prices for wheat.

B.—COSTS OF GROWING OATS IN ROTATION WITH WHEAT.

1. Introductory.

The experience of many years has shown that it is not as a rule safe to sow successive crops of wheat on the relatively light soils of our Mallee Areas without interposing to each crop not only one year of carefully tilled bare fallow, but in addition a crop of oats. The apparent role of the oat crop in the matter seems to be to crowd out plants, such as barley grass, that act as hosts to the Take-all fungus (*Ophiobolus graminis*) and contaminate the soil for the succeeding wheat crop. The value of this practice is particularly noticeable in the early years of reclamation, when the land is still crowded with decaying roots and stumps, in the midst of which wheat plants appear less able to resist "Take-all" than under more normal conditions of farming. Hence, rotations of the following types, involving wheat on the same area of land not more frequently than once in every three or four years, have become more or less standardised in most Mallee Districts.

	ROTATION "A."	ROTATION "B."
1st year	Bare fallow	Bare fallow
2nd year	Wheat	Wheat
3rd year	Oats	Oats
4th year	Bare fallow	Grazing
5th year	Wheat, &c.	Bare fallow, &c.

Rotation "A" (with wheat once in three years) is admissible only on moderate loams that are to all intents and purposes adequately cleared of roots and stumps.

Rotation "B" (with wheat once in four years) is typical of what is usually practised on the lighter types of soil; not infrequently the rotation is extended to a fifth year by a second year of grazing.

On Mallee Farm No. 1 the owner has followed the practice of sowing oats partly on wheat stubbles or grassland and partly on bare fallow.

2. Mean Costs of Growing Oats on Grass Land.

Oats were sown on grass land in two seasons only, namely, in 1929-30 and in 1930-31; full details of mean expenditure incurred have been set out in Table VIII. of the Appendix; this Table consists of three parts, namely:—

Part I.—Detailed analysis of expenditure incurred in growing oats in 1929-30 and 1930-31 on a mean area of 90.5 acres, the mean yield from which was 9.63 bushels per acre.

Part II.—Calculated costs per acre of the above.

Part III.—Calculated costs per bushel of the above.

Table VIII. shows that the mean costs per bushel of growing 90.5 acres of oats, yielding 9.63 bushels per acre, was 4s. 5½d.; such costs are clearly uneconomic, since the mean metropolitan wholesale price of oats for the five-year period closing in 1932 was 2s. 8½d. per bushel only. The main cause of these uneconomically high per bushel "costs" was the low mean yield per acre, which again was attributable to a very unfavorable season in 1929-30. In order to make this point clear the main features of each season have been summarised below:—

Seasons.	Areas Sown. Acres.	Mean Yields.	Mean Costs.	
		Per Acre. Bush.	Per Acre. £ s. d.	Per Bushel. s. d.
1929-30	120	5.52	1 19 4	7 5½
1930-31	61	17.70	2 9 10	2 9½
Means	90.5	9.63	2 2 11'	4 5½

Hence, in a relatively favorable season the oat yield off grass land on Mallee Farm No. 1 was 17.7 bushels per acre, at a cost of 2s. 9½d. per bushel; whereas in an unfavorable season it was 5.52 bushels and 7s. 1½d. respectively. Attention has already been drawn to the fact that experience had shown the expediency in Mallee districts of separating two successive crops of wheat on the same land by an intervening crop of oats, and particularly so in the early stages of settlement; and it follows that mean returns from the rotation as a whole are of greater concern to the farmer than the mean returns of individual crops. Thus, since it must be admitted that unlike the South-East, our Mallee Districts do not usually offer ideal conditions for the growth of oat crops, it might at times be hoped that weaknesses in oat returns might be countered by strength in wheat returns. Unfortunately, although in certain circumstances such a hope can and has been justified, in the present period of low prices for all agricultural products the rotation is bound to fail unless everyone of its members can stand on its own legs; in other words, the Mallee can no longer afford to grow oats at a loss in the hope that a succeeding wheat crop will more than make good the loss.

In this connection, not even the favorable 1930-31 season with its 17.7 bushels of oats to the acre at a cost of 2s. 9½d. can meet the requirements of Mallee Farm No. 1; actually, these costs correspond to 3s. 2d. per bushel, on trucks, Port

Adelaide, and it has already been stated that the mean metropolitan wholesale price for oats for the five years ending in 1932 was 2s. 8½d. only. But it is often urged that oats need not necessarily be sold as such; that they can be fed to advantage to cattle, horses, and sheep; all this might be true provided the oats could be grown at a cost that did not render their use prohibitive. Oats that have cost 7s., 4s., or even 3s. to grow are not likely to prove cheap foodstuffs, even on the farm on which they have been raised. The man who elected to grow oats for his livestock at a cost of 4s. to 5s. a bushel instead of purchasing them from his neighbor at 2s. to 2s. 6d. is in the same position as the suburban gardener who imagines that his back yard cabbages are a sounder proposition than his purchases from the greengrocer.

Nevertheless, in present circumstances it seems almost inevitable that the Mallee wheat farmer should have to grow occasional oat crops; and as costs per acre cannot very well be reduced it remains to be seen what mean yield of oats per acre would be likely to prove directly profitable in the Mallee.

If in this connection we assumed—as we well might—that the mean costs per acre of the 1930-31 Mallee Farm No. 1 oat crop, namely, £2 9s. 10d., remained the same, apart from successive harvest cost increases, we should find that the successive costs per bushel of progressively increasing oat yields would be as follows:—

		s.	d.
Recorded mean costs per bushel of	17.7bush. crop	2	9½
Calculated mean costs per bushel of	20.0bush. crop	2	6½
Calculated mean costs per bushel of	21.0bush. crop	2	5½
Calculated mean costs per bushel of	22.0bush. crop	2	4½
Calculated mean costs per bushel of	23.0bush. crop	2	3½

Thus, it is not until we reach a mean yield per acre of 23 bushels that we can count upon costs per bushel that would be appreciably lower than the parity of the mean metropolitan wholesale price, 2s. 8½d. The calculated costs per bushel of a 23bush. crop are shown to have been 2s. 3½d. per bushel, which is equivalent to 2s. 7½d. on trucks, Port Adelaide, that is to say, 1d. lower than the mean metropolitan wholesale price. Such a mean yield is not impossible even in the Mallee; in many instances more thorough, more careful, handling of the crop is all that would be necessary.

But in the meanwhile, we are bound to recognise that it is miles ahead of the mean yields of oats usually grown on stubbles or grassland of Mallee districts. For the five-year period closing in 1932, the mean yield of oats, whether on fallow or on grass or stubble land, was 5.28 bushels per acre for County Chandos, and 5.15 bushels per acre for the Murray Mallee Division. Yields such as these are clearly uneconomic, and it is questionable whether even the ravages of take-all can justify the costs and wasted effort they have entailed of recent years. I propose discussing this question further after considering the costs of growing oats on bare fallow.

3. Mean Costs of Growing Oats on Bare Fallow.

In 1929-30 oats were sown on 15 acres of bare fallow and in 1931-32 on 33 acres of bare fallow; the mean yields per acre were 18.35 bushels in 1929-30 and 15.15 bushels in 1931-32.

Mean expenditure incurred during these two seasons has been analysed in detail in Table IX., Part I., for a mean area of 24 acres and a mean yield of 16.15 bushels per acre.

In Parts II. and III. of the same Table the mean expenditure has been expressed as mean costs per acre and mean costs per bushel respectively.

The data of Tables VIII. and IX. respectively have been summarised below under Statements "A," "B," and "C":—

Comparative Summarised Statements of Costs of Growing Oats on Grass Land and Bare Fallow respectively.

	Oats on Grass Land (1929-31).			Oats on Bare Fallow (1929-30 and 1931-32).		
	Mean Yield per Acre 9.63 Bush.			Mean Yield per Acre 16.15 Bush.

Interest on Overdraft ...	0 5	0 1	1.0	0 10	0 1	1.4
Interest and Depreciation Charges	15 0	1 6	34.9	24 10	1 6	43.5
Balance of Expenditure .	27 11	2 11	65.1	32 3	2 0	56.5
Totals	42 11	4 5	100.0	57 1	3 6	100.0
*Labor (direct)	6 1	0 7.5	—	9 11	0 7.5	—
Labor (indirect)	1 2	0 1.5	—	3 2	0 2.5	—
	7 3	0 9	—	13 1	0 10	—

From the above statements we see that although a 16.15 bushel crop of oats grown on bare fallow cost 14s. 2d. per acre more than a 9.63 bushel crop of oats grown on grass land, the costs per bushel were 3s. 6d. for oats on fallow and 4s. 5d. for oats on grass land. Nevertheless, 3s. 6d. per bushel on the farm is considerably above the local parity of the mean metropolitan wholesale price of oats, namely, 2s. 4½d., on the farm; nor for oats sown on bare fallow are costs of 2s. 4½d. per bushel or less attainable, except for mean yields of not less than 30 bushels per acre. Mean yields of oats of 30 bushels and more cannot be expected in the Mallee for the present, at all events.

THE CHAMPIONSHIP WHEAT CROP COMPETITION.

(Won by Mr. Henry Michael, Hilltown.)

In his report on the Championship Wheat Crop Competition for the season 1933-34, Mr. W. J. Spafford (Deputy Director of Agriculture), who judged the entries, stated that for the past 10 years Wheat Crop Competitions, supervised by the Department of Agriculture, have been conducted in South Australia. For the first six seasons the Government subsidised these competitions but, unfortunately, found it necessary to discontinue the subsidy, with the inevitable result that the number of entries received show a decrease on those years when financial aid was given. A generous donation of £100 made by the S.A. Farmers' Co-operative Union Limited, which has been distributed amongst 19 district committees which conducted crop competitions *pro rata* to the number of entries received and paid for, proved of considerable help in maintaining interest in the crop competitions.

The Department of Agriculture supplies the judges, who inspect the crops, make the awards, and prepare reports on all entries in the competitions.

Until the end of September the wheat crop of the State was the most promising yet grown, and it appeared at that time that there was every probability of a record yield much greater than any yet harvested. The lack of rain in October and early November, however, proved serious to most crops and disastrous to many, and reduced the yields to a point considerably below what were anticipated. As is usual in seasons when the spring is dry, the only crops to mature properly were those grown on good fallow, and some very striking instances of this were to be seen in most parts of the State, and were particularly noticeable in the lower rainfall districts.

The want of improvement in the price of wheat, the general depression, and the dry spring militated against the chances of a great number of entries in the crop competitions, nevertheless, 19 districts conducted competitions, and 351 crops were judged. In four of the competitions the judges decided that the winning crop was not sufficiently good to leave in the Championship, so this year only 15 crops were included in the competition.

Table Showing Progress of Wheat Crop Competitions.

Year.	Districts Conducting Competitions.	Number of Crops Exhibited.
1924	12	290
1925	13	248
1926	17	444
1927	19	525
1928	22	634
1929	21	520
1930	19	473
1931	16	352
1932	20	385
1933	19	351

In 1927 the Royal Agricultural and Horticultural Society offered as a prize in connection with Wheat Crop Competitions, conducted under the auspices of the Department of Agriculture, a silver challenge shield of the value of 50 guineas, and annually a small replica of the shield valued at five guineas. The Royal Society had in view the offer of special assistance in the encouragement of Wheat Crop Competitions, and in accepting the generous offer the Government agreed to conditions laid down by the society, which were as follows:—

1. The prizes go to the person exhibiting the best crop in the competitions supervised by the Department of Agriculture, the silver challenge shield for a period of 12 months immediately succeeding the award, and the silver replica to become the absolute property of the winner.

2. The challenge shield, with the name of each year's winner engraved thereon, to be exhibited in the town hall or institute nearest the farm on which the winning crop was grown.

3. The crop awarded first prize in each supervised district competition to be taken as an entry for the Championship Competition, except in any case in which it is thought by the judge of the district competition that the winning crop is not of sufficient merit to warrant inspection for the championship trophy.

4. All entries for the championship to be inspected by one judge. Such inspection to be undertaken in each district soon after the district judge has made his awards, but not before the crop has ripened.

5. Each competitor for the championship to be required to stage one bag of grain and one sheaf (about 1ft. in diameter) of grain in the straw at the Royal Spring Show following the competition.

WINNERS OF THE CHAMPIONSHIP WHEAT CROP.

- 1927. F. V. Trenorden, Bordertown. (Federation wheat.)
- 1928. F. Coleman, Saddleworth. (Leak's Rustproof and Fondling wheats.)
- 1929. F. V. Trenorden, Bordertown. (Bena wheat.)
- 1930. H. C. M. Pilgrim, Wolseley. (Gallipoli wheat.)
- 1931. A. M. Dawkins, Gawler River. (Ford wheat.)
- 1932. J. P. Carrigg, Hamley Bridge. (Sword wheat.)
- 1933. H. Michael, Hilltown. (Dan wheat.)

THE ENTRIES.

All of the 15 crops in the Championship Crop Competition were well grown, and their inclusion in this important competition was thoroughly warranted, but some of the most promising of them had matured too rapidly under the peculiar ripening conditions that prevailed, with the result that the yields were reduced because of the shrivelling of the grain. A good deal of difficulty was experienced in placing the best of the crops in the correct order of merit because of their general excellence as competition crops, and all of them reflect credit on the farmers who produced them.

THE AWARDS.

In reporting on the entries it has been decided to follow the practice of other years of indicating the crops which would have been placed second and third to the winner of the championship trophy had this been an ordinary competition, but the other crops are not shown in order of merit, and where any remarks are made on their crops the exhibitors' names are placed in alphabetical order, and not according to points awarded. The awards and a brief description of the crops submitted in the competition are set out below:—

THE CHAMPIONSHIP WHEAT CROP (DAN WHEAT.)

H. Michael, Hilltown.

This excellent crop of Dan wheat won the Championship Wheat Crop Competition for Mr. H. Michael, of Hilltown, after having been placed first in the Midlands District Competition. It was a heavy-yielding crop, very even in growth, and a good competition crop in every way. Very few weeds of any kind were present, there being only isolated plants of spear thistle, saffron thistle, and wild oats, and the crop was practically disease free. Although there was a light sprinkling of a wheat which was taller than Dan and an odd plant or so of a brown-chaffed wheat, the crop was quite good as regards trueness to type. The growth was even and regular, and there were no drill misses.

The fallow on which the crop was grown was preceded by a wheat crop which was also grown on fallow, but the fallow of 1930 followed a crop of oats grown on land that had been rested as pasture in the previous year. In 1932 the block was fallowed in July, cultivated in August, October, and April, and during the first week in June 90lbs. of graded and dry-pickled seed and 105lbs. super-phosphate (48 per cent.) were put in to the acre with a combine.

The manner in which weeds had been got under control and the regularity of the growth of the crop shows that Mr. Michael is highly skilful as an agriculturist, and this beautiful crop is a great credit to him, and he is deserving of the highest praise for its general excellence.

THE OTHER PLACED CROPS.

FISHER BROS., Bordertown (Ranee).

The crop of Ranee which won the Tatiara Wheat Crop Competition for Messrs. Fisher Bros., of Bordertown, was a very attractive crop, and did well in the Championship Competition. There were a few patches as well as scattered plants of wild oats, and just a few plants of silver grass and brome grass, nevertheless the crop was nice and clean. Besides being practically disease free the crop was really true to type for the old-time Ranee, as it only showed odd plants of the bearded throw-back. There were no drill misses, but the crop was a little uneven as far as density was concerned.

The field in which the crop was grown had been farmed as—(a) pasture, (b) fallow (c) wheat, (d) oats, (e) fallow, previously to being seeded to the Ranee. The land was ploughed 3½ in. in depth with a mouldboard plough in August, harrowed in September, cultivated in October, January, April, May, and early June, and during the third week in June 75lbs. of graded and dry-pickled seed was put in with 125lbs. of superphosphate per acre with a combine which was followed by harrows a few days afterwards.

The field was obviously well farmed, and such a good crop could only have resulted from careful and intelligent work.

J. D. CAMPBELL, Barabba (Sword).

The Balaklava Crop Competition was won by Mr. J. D. Campbell with this crop of Sword wheat, which was so clean that it was almost weed free, only containing isolated plants of mustard. The only diseased plants to be seen were a few suffering from loose smut, and it was much truer to type than most crops of Sword in that it only contained a light sprinkling of the dark-chaffed wheat usually found in this variety. The crop had been drilled in carefully, and although there were a few small patches a bit weaker than the bulk of the crop it was nice and even. The grain was not quite as good as might have been, due to the crop maturing a little too rapidly in the long spell of dry weather experienced.

The field on which the crop was grown has been farmed on the system of—(a) fallow, (b) wheat, (c) pasture, for some years now. The land was ploughed towards the end of June, cultivated twice, and harrowed three times before harvest, cultivated in early May, and in the middle of May 63lbs. of graded and dry-pickled seed and 1cwt. superphosphate (45 per cent.) were sown to the acre with a combine.

This was an extremely good competition crop, but would have been much better had it not ripened too quickly which reduced the yield to a noticeable extent.

OTHER ENTRIES (IN ALPHABETICAL ORDER).

W. H. & J. ALDERMAN, Minlaton (Ford).

The first-prize crop in the Southern Yorke Peninsula Competition was this crop of Ford grown by Messrs. Alderman Bros., and although it had a few patches of wild oats and a few plants of mustard and soapwort was really clean. The presence of a few plants affected with bunt lowered the marks given, but otherwise the crop was disease free. There was a fairly heavy sprinkling of a brown-chaffed wheat and a few King's White plants. There were no drill misses, and the crop was even throughout, and was carrying really good quality grain, showing no ill effects of the severe ripening season.

The land carrying the crop had been farmed for some years on the three-course rotation of—(a) fallow, (b) wheat, (c) barley, and this crop was sown on fallow by putting in 90lbs. seed and 120lbs. superphosphate to the acre with a combine during the third week in May.

A. BEELITZ, Parrakie (Waratah).

With this crop of Waratah Mr. Beelitz won the Chandos Crop Competition, and although it contained a few plants of mustard, wild oats, and brome grass, and a couple of barley plants, it was a very clean crop. There was a fair amount of flag smut present, and a few very small patches of take-all. The crop was nice and true to type, only containing a light sprinkling of a white-chaffed wheat. A few small drill misses were noticeable, and the crop was somewhat lighter one end than the other, and on the whole good grain had matured over most of the crop.

Of recent years the field carrying the crop has been farmed as—(a) pasture, (b) fallow, (c) wheat, (d) oats, (e) fallow, and for the crop under review the land was fallowed in July, 1932. In the second week in June 60lbs. of seed and 1cwt. superphosphate per acre were drilled in.

C. G. & G. W. CANT, Kimba (Gluyas).

This crop of Gluyas, which won the Buxton Crop Competition for Messrs. Cant Bros, was so clean that it was only possible to find a few mustard plants scattered here and there. The only disease doing damage was flag smut, and it was quite prevalent. Although there was a sprinkling of King's White and a white-chaffed beardless wheat the crop was very fair as regards trueness to type. The crop was well drilled, and so far as evenness was concerned was very fair.

For some years the field producing the crop had been farmed on the rotation of—(a) fallow, (b) wheat, (c) oats, and in 1932 the land was fallowed in June, cultivated in September and March, and towards the end of May 60lbs. of graded and dry-pickled seed and 70lbs. of superphosphate (48 per cent.) were put in to the acre with a combine.

S. C. CRAWFORD, Strathalbyn (Ford).

The Southern Crop Competition was won by this crop of Ford grown by Mr. Crawford, and except for the presence of a lot of Wimmera rye grass in patches and a couple of plants of barley it was free from weeds. Only one hunted plant was seen, otherwise it was a disease-free crop. Although there was a light sprinkling of a brown-chaffed wheat and isolated woolly plants, the crop was more nearly true to type than most crops of Ford being grown. Other than a few drill misses the crop was very regular and even.

The system of cropping followed of recent years has been—(a) fallow, (b) wheat, (c) oats, (d) pasture, (e) fallow, and the fallow prepared in 1932 was sown with a combine in early June, using 80lbs. of seed pickled with bluestone and 120lbs. superphosphate per acre.

T. W. DAY, Reeve's Plains (Sword).

Although this crop of Sword, which won the first-prize trophy in the Central Crop Competition, matured too rapidly, it was still a really good wheat crop at harvest time. There were some patches of three-cornered jacks, wild oats, and burr clover, and odd plants of mustard; still the crop was very fair as regards cleanliness, and it was almost disease free, although three bunt plants and a little loose smut were found. It was only fair as regards trueness to type, containing a sprinkling of a brown-chaffed wheat and a purple-strawed kind. The crop was well drilled and was even throughout.

Since 1927 the system of cropping the field has been—(a) fallow, (b) wheat, (c) barley, (d) barley, (e) fallow, and to carry this crop the land was ploughed in August, harrowed in September and twice in October, cultivated at the end of October, harrowed in April, and early in May 90lbs. of re-winnowed seed and 90lbs. superphosphate (45 per cent.) were sown to the acre with a combine.

E. H. HAMPEL, Terka (Onas and Currawa).

For his entry which was successful in the Upper North Crop Competition Mr. Hampel exhibited 35 acres of Onas and 15 acres of Currawa. In both crops wild oats were fairly thick, and there were a few plants of mustard, yet if it had not been for the oats the crops would have been clean. The Onas was affected by flag smut very badly, and there were a few small patches with take-all, but with the Currawa it was almost disease free, and only showed a few plants with flag smut. The Onas was true to type except for a few isolated plants of a kind a bit taller, whereas the Currawa was far from good. There were no drill misses, but the crops were rather irregular owing to the varying nature of the soil on which they were grown.

The land has been frequently cropped of recent years on the bare fallow—wheat—bare fallow—wheat rotation. The land was ploughed at the end of the winter, harrowed in September, cultivated twice in October, again in May, and then was seeded with a combine using 60lbs. graded and dry-pickled seed and 90lbs. superphosphate per acre, and the lot was then harrowed.

R. KAIN, Yeelanna (Waratah).

The Flinders Crop Competition was won by Mr. Kain with this crop of Waratah which was very fair as regards cleanliness, although there was some drake, mustard, and poppy, and odd plants of wild oats and spear thistles. At one corner of the block were to be seen a fair number of take-all patches, and a few plants were affected with flag smut. There was hardly any admixture of any kind in the crop, and it was really true to type. Although there were a few misses by the drill the crop was fairly regular and even.

The fallow on which the crop was grown followed the course of cropping of—(a) fallow, (b) wheat, (c) oats for grazing, and was prepared by ploughing in July, was harrowed and cultivated in September, cultivated in October and May, cultivated and harrowed in early June, and about June 20th was sown with 70lbs. graded and dry-pickled seed and 150lbs. superphosphate per acre.

ALEX. MAITLAND, Rochester (Nabawa).

Although this crop of Nabawa which won the Mid-North Crop Competition for Mr. Maitland contained wild oats scattered throughout it, some sheep weed and a few odd plants of mustard, poppy, and turnip, it was fairly clean, and as far as could be seen it was free from injurious diseases. There was a light sprinkling of a brown-chaffed wheat, but the crop was very fair as regards trueness to type. There were no drill misses, and the crop was very even and regular.

The field has been worked on the system of—(a) fallow, (b) wheat, (c) pasture for some time now, and the fallow on which this crop was grown was mouldboard ploughed in June, harrowed in July and twice in August, cultivated in August, October, and April, and harrowed in April. At seeding 80lbs. graded and dry-pickled seed and 90lbs. superphosphate (45 per cent.) were used per acre.

ELDER'S Trustee and Executor Company Limited.
35, CURRIE STREET, ADELAIDE.

L. NORTHEY, Thrington (Sword).

The crop grown by Mr. Northey, which won the Northern Yorke Peninsula Crop Competition, consisted of Sword, and was still a good crop despite the fact that it had matured a bit too quickly because it had been sown a little on the early side. It contained a few patches of wild oats and barley grass, and a few plants of mustard and poppy, nevertheless it was a fairly clean crop. No injurious diseases were in evidence. There was a fair amount of admixture of other varieties. It was an even and regular crop, and only showed a couple of drill misses.

The field had been worked as fallow in 1928, carried wheat in 1929, then a crop of oats, then wheat, and in 1932 was ploughed in July, cultivated in September and April, cultipacked before seeding, which was done with a combine in the middle of May by putting in 70lbs. of graded seed and 60lbs. superphosphate (45 per cent.) to the acre.

G. F. PEARCE, Maitland (Ford).

The Mid-Yorke Peninsula Crop Competition was won by Mr. Pearce with this crop of Ford, which was a fairly clean crop, although it contained mustard and wild oats in patches, and a sprinkling of spear thistles. It was apparently disease free, and was very fair as far as trueness to type goes, only showing a light sprinkling of the brown-chaffed wheat usually found in Ford. There were a few drill misses, and the crop was only fairly regular.

In the four years preceding the fallow which carried this crop the land was worked for fallow, wheat, barley, and barley. In the first week of June, 1933, 90lbs. of graded and dry-pickled seed and 150lbs. superphosphate were sown to the acre with a combine.

J. SIMS, Cleve (Felix).

Felix grown by Mr. Sims secured first-prize trophy in the Jervois Crop Competition, and except for the fact that it had a light sprinkling of barley throughout it was a very clean crop, there being present only a few plants of mustard and wild oats and isolated plants of poppy and soapwort. There were a few plants affected with flag smut, an isolated case or two with loose smut, and most of the plants had the appearance of having had an attack of spotted rust. There was a very light sprinkling of King's White wheat in the crop, but it was quite good as regards trueness to type. As well as a few drill misses there were a lot of water runs, and so the crop looked more irregular than was actually the case.

The land should have been in good heart, because the cropping which preceded this one had been light, for in 1928 it was fallowed, then carried wheat, was rested for two years as pasture, and was then fallowed in 1932 by mouldboard ploughing in early June, was harrowed in August, skim-ploughed in September, harrowed in May, and during the first week in June 55lbs. of re-winnowed seed which had been pickled with bluestone and 95lbs. superphosphate (45 per cent.) were seeded to the acre, and the land immediately harrowed.

W. F. WURST, Laura (Nabawa).

This very clean crop of Nabawa wheat which only contained a few plants of wild oats and sheep weed won the Northern Crop Competition for Mr. Wurst, of Laura. Besides being clean the crop was also free from noticeable injurious diseases. There was not much admixture in it, and only a few brown-chaffed heads and isolated plants with white chaff or bearded were to be seen. There were a few drill misses that were not serious, but the crop varied from an extremely heavy-yielding crop on the more friable land to a lighter crop on the red land.

The land has been worked on the fallow—wheat—fallow—wheat rotation for some time now, and the 1932 fallow was harrowed in September, cultivated twice in October and again in May, and was sown in May with a combine, using 56lbs. of graded and dry-pickled seed and 90lbs. superphosphate (45 per cent.) to the acre, and was then harrowed twice.

FACTORS AFFECTING THE SEVERITY OF TAKE-ALL.

[By S. D. GARRETT, B.A., Assistant Plant Pathologist, Waite Agricultural Research Institute, University of Adelaide.]

(Continued from page 674.)

2. SOIL TEMPERATURE.

The first work upon the effect of soil temperature on take-all was that of McKinney and Davis (⁴), who showed by means of experiments in soil temperature tanks that the disease was most severe at low soil temperatures (12°-16° C.)*.

This was confirmed by the work (unpublished) of G. Samuel at the Waite Institute in 1926 and 1927. A South Australian culture of the take-all fungus, *Ophiobolus graminis*, was used, and the wheat seedlings were grown in a mixture of two parts of Glen Osmond red loam to one of sand, steam sterilised before use. The inoculum was 50 grams of a culture of the fungus on oat-barley kernel medium. Infection was recorded by the method of McKinney and Davis after four weeks. The infection ratings obtained in one experiment are given in Table I., and infection curves for the roots only are plotted in Fig. 3 (a). A photograph of plants from the 45 per cent. moisture series at the end of the experiment is given in Fig. 4 (a). The results agree well with those of McKinney and Davis.

TABLE I.—Infection of Federation Wheat Seedlings at Different Soil Temperatures in Glen Osmond Loam.

Temperature.	Moisture in per cent. sat.	Leaf-blight.	Percentage Infection. Tiller-bases.	Roots.
30°C	75	0	0	3
	45	0	0	5
25°C	75	17	28	33
	45	53	57	78
20°C	75	77	95	92
	45	85	100	97
15°C	75	87	100	100
	45	85	100	100
10°C	75	80	100	93
	45	83	100	100

At the time these experiments were done no satisfactory explanation of the behavior of take-all in relation to soil temperature could be advanced. It was known that the growth of the take-all fungus in culture was most vigorous at the higher temperatures (optimum about 25° C.). It was also known from the work of J. G. Dickson and his collaborators (^{1, 2}) that wheat was most vigorous at low temperatures (12°-16° C.), and better able to resist the invasion of the wheat scab fungus (*Gibberella saubinetii*). At higher temperatures (25°-30° C.) the composition of the roots was found to change in such a way as to decrease their resistance to infection by this fungus. Unless the take-all fungus differed markedly in its parasitism from the scab fungus it was difficult to see why wheat plants should not also suffer more from take-all at higher temperatures, at which the wheat plant would be less vigorous and the take-all fungus more vigorous.

* Temperatures in this paper are given in degrees Centigrade, but the following table will enable a rough deduction of the Fahrenheit temperatures to be made from the Centigrade:—

10°C=50°F. 15°C=59°F. 20°C=68°F. 25°C=77°F. 30°C=86°F.

This puzzling situation was largely cleared up by the appearance of a paper by A. W. Henry ⁽³⁾ on "The influence of soil temperature and soil sterilisation on the reaction of wheat seedlings to *Ophiobolus graminis*." Henry found that in unsterilised soil infection fell off with rise of temperature from 18° to 27° C., as found by McKinney and Davis, but that in sterilised soil infection actually increased with rise of temperature (see Fig. 3 (b), a reproduction of Henry's curves for root infection in sterilised and unsterilised soil). The decrease in

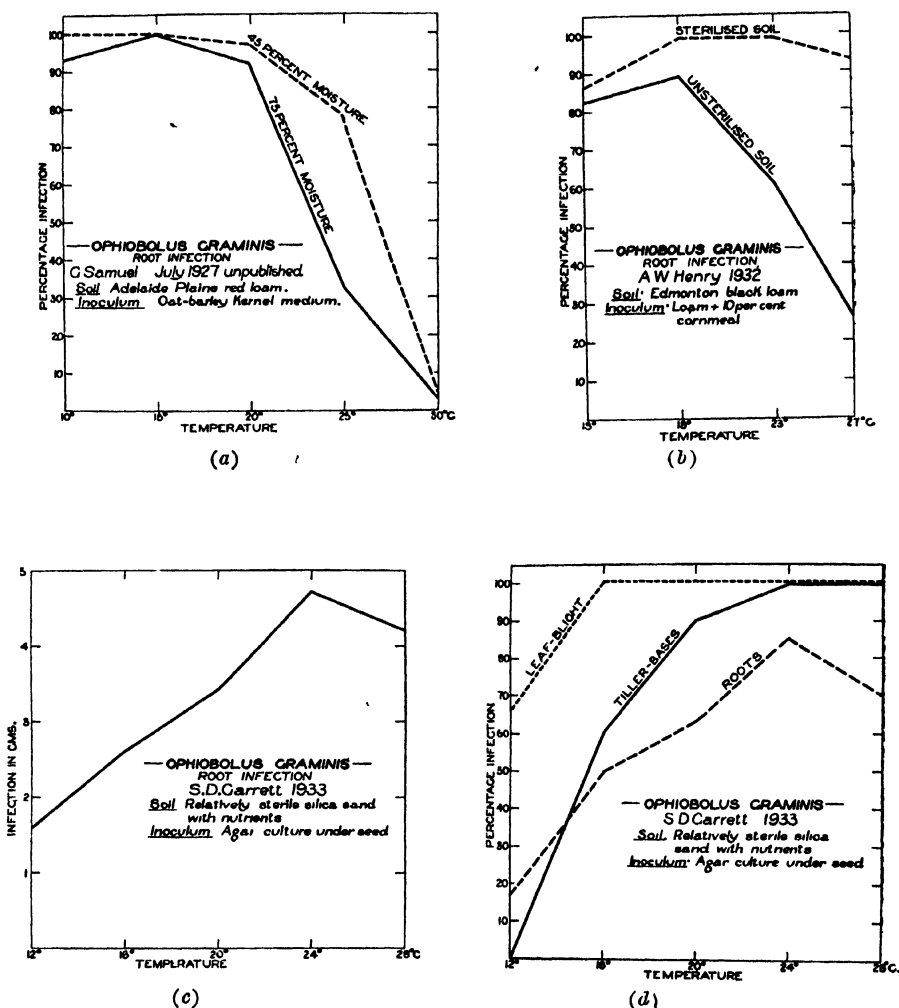

Fig. 3.—Graphs showing the relation of soil temperature to infection of wheat seedlings by *Ophiobolus graminis* under different soil conditions.

infection with rise of temperature in the unsterilised soil was attributed by Henry simply to the antagonism of the other soil organisms to *Ophiobolus*, which he considered to be negligible at 12° C., but very much more active at 25° C. When the other soil micro-organisms were absent, as was the case in the sterilised soil, the true effect of temperature appeared, and infection increased from 12° C. upwards.

McKinney and Davis employed sterilised soil in their experiments, and the soil from the 1926 and 1927 experiments at the Waite Institute was also sterilised. Sterilised soil rapidly reverts to the non-sterile condition, however, and the use of an oat-barley kernel inoculum probably hastens the process considerably. The rapidity with which micro-organisms establish themselves in an experimental soil must also vary with the type of soil and with the degree of sterilisation as well as with the subsequent treatment. Henry did not give details of the soil he used. If it was Edmonton black loam it hardly seems likely that the biological factor would have been completely eliminated throughout the course of his experiments.

Since it was found from the work described in Part I. of this paper that the effect of the biological factor was very slight in Gawler River sand, even when not

Fig. 4. (a)—Plants from a soil-temperature experiment in clay-loam soil inoculated with a culture of *Ophiobolus graminis* on an oat-barley kernel medium. Biological antagonism has caused infection to fall off with rise of temperature.

sterilised, it was decided to repeat the soil temperature work, using this sand in place of soil. It was hoped in this way to secure a more complete elimination of the complicating effects of soil bacteria, and so to obtain a closer approach to the true form of the temperature-infection curve.

EXPERIMENT ON THE EFFECT OF TEMPERATURE UPON INFECTION OF WHEAT SEEDLINGS UNDER RELATIVELY STERILE CONDITIONS.

Untreated Gawler River sand was employed. It was not sterilised, since previous experiments had shown that sterilisation resulted in only a slight increase of infection. The sand was brought to a moisture content of 50 per cent. saturation

by the addition of a nutrient solution (to secure the best growth of the plants). Four 8 in. containers were filled with the moist sand for each of the five soil temperatures employed, viz.:—12°, 16°, 20°, 24° and 28° C. Fifteen seeds were planted in each container, and three containers were inoculated in each tank by placing a small block of the fungus growing on agar under the seed at planting. After 14 days the plants from one container in each tank were washed out, and infection recorded by measuring the growth of the mycelium down the roots. The results are shown in Table II. and in Fig 3 (c).

TABLE II.—*Infection of Federation Wheat Seedlings at Different Soil Temperatures, in a Silica Sand, with Nutrients, after Two Weeks.*

Temperature.	Mean Infection in cms. from Seed.	Standard Error of Mean.	Difference of Means.
28°C	4.2	0.25	0.5 ± 0.35
24°C	4.7	0.25	1.3 ± 0.3
20°C	3.4	0.17	0.8 ± 0.2
16°C	2.6	0.105	1.0 ± 0.1
12°C	1.6	0.063	

Fig. 4. (b)—Plants from a soil-temperature experiment in practically sterile sand; inoculation by means of a small block of an agar culture of *Ophiobolus graminis* placed beneath the seed. Biological antagonism almost eliminated; infection increased with rise of temperature to 24° C.

After 28 days the degree of infection in the remaining plants was recorded by the method of McKinney and Davis; the results are shown in Table III., and infection curves plotted in Fig. 3 (d). A photograph of the plants at the end of the experiment is shown in Fig. 4 (b).

TABLE III.—*Infection of Federation Wheat Seedlings at Different Soil Temperatures in a Silica Sand after Four Weeks.*

Temperature.	Leaf-blight.	Percentage Infection.	
		Tiller-bases.	Root.
28°C	70	100	100
24°C	85	100	100
20°C	63	90	100
16°C	50	60	100
12°C	17	0	66

It will be seen from Figs 3 (c) and 3 (d) that the two methods of recording infection agree quite well. It is also evident that when soil bacteria are excluded as much as possible by the use of a silica sand in place of soil, the take-all disease increases in severity with increasing temperature up to 24° C. This confirms the work of Henry. The slight fall in infection at 28° C. is probably due to the decrease in growth rate of the fungus at this temperature (optimum temperature for growth of *Ophiobolus graminis* on agar, 25° C.).

EXPERIMENT ON THE EFFECT OF TEMPERATURE ON THE VIABILITY OF *Ophiobolus* INOCULUM IN SOIL.

Since soil bacteria had been found to have such a depressing effect on the infection of wheat seedlings by the take-all fungus at high soil temperatures, a test was made to determine whether a heavy inoculation of take-all mycelium in soil would be greatly reduced in amount at high temperatures in the absence of wheat seedlings. A culture of the fungus upon cornmeal-sand medium (containing 2 per cent. cornmeal by weight) was mixed up with its own weight of Glen Osmond soil partially sterilised by steam. The mixture was brought up to a moisture content of approximately 50 per cent. saturation, and filled into six tumblers. Three tumblers were then maintained at 25° C., and the other three at 12° C. for 14 days. At the end of this time the viability of the inoculum in the two series was compared by planting all tumblers with wheat seeds, and keeping them together at 12° C. After a further 28 days the plants were washed out for an examination of the roots.

Whereas in the 12° series infection was continuous over the entire length of the roots, in the 25° series it was restricted to a number of scattered lesions. This is clearly shown by a drawing of typical root systems from each series (Fig. 5 (b)). A photograph of the plants growing in the tumblers is also shown (Fig. 5 (a)); this gives some idea of the differences in severity of infection in the two series. It is thus evident that *Ophiobolus* inoculum degenerates much more rapidly in the soil at 25° C. than at 12° C. This is probably mainly due to the antagonistic effect of soil micro-organisms at the higher temperatures.

DISCUSSION.

The above experiments give satisfactory confirmation of Henry's work and, indeed, scarcely call for additional comment. When the microbiological factor is excluded (in the present case by the use of silica sand in place of soil), the infection curve for take-all rises steadily with increase of temperature to 24° C., which corresponds to the optimum temperature for the vegetative development of the parasite. When, on the other hand, biological antagonism is allowed full scope by the nature of the soil and the method of inoculation, infection falls off rapidly at the higher temperatures.

It seems likely, therefore, that in soils with a naturally poor microbiological content, such as the Mallee sands, take-all infection may be accelerated by rise of temperature. This may account for the appearance, in some seasons, of patches of take-all in the white-head stage as late as September or October. These may be patches of primary infection in which symptoms of disease did not show up during the winter, when the low soil temperatures (in the region of 10° C.) are favorable to root growth of the wheat plant, and hold the take-all fungus in check

Fig. 5.—Experiment to show that degeneration of cornmeal-sand inoculum of *Ophiobolus graminis* in loam soil is accelerated by rise of temperature from 12° to 25° C.

Fig. 5. (a)—Plants after four weeks' growth in inoculated soil, which was kept for two weeks prior to planting at 12° C. (left), and at 25° C. (right).

to some extent. With the advent of warm weather in spring the higher temperatures depress root production by the plant, and at the same time accelerate the activity of the fungus, with the result that infection makes rapid progress and the plants bleach off as "white-heads."

Finally, the effect of high temperatures (25° C. and above) in accelerating degeneration of *Ophiobolus* inoculum in moist soil has been directly proved by experiment. There is little doubt that the disappearance of take-all in fallows on the heavier soils is largely due to the operation of this factor.

SUMMARY FOR PART II.

Experiments are described confirming the work of A. W. Henry on the effect of soil temperature upon infection of wheat seedlings by the take-all fungus.

When the other soil micro-organisms were practically excluded by the employment of a sterile silica sand, with seed inoculation, infection by the take-all fungus increased steadily with rise of temperature from 12° to 24° C., the optimum temperature for growth of the fungus in pure culture.

It was shown that degeneration of *Ophiobolus* inoculum in soil is much more rapid at 25° than at 12° C.

Fig. 5.—Experiment to show that degeneration of cornmeal-sand inoculum of *Ophiobolus graminis* in loam soil is accelerated by rise of temperature from 12° to 25° C.

Fig. 5. (b) Typical root systems from the two series, showing the extent of infection (in black).

It is suggested that in soils with a poor microbiological content, such as the Mallee sands, take-all infection is accelerated by rise of temperature, and that this is a factor contributing to the late appearance of the disease in some seasons, when primary soil infection does not show up until the crop is already in ear.

DAIRY INDUSTRY PRICES.

ROYAL COMMISSION REPORT TO HIS EXCELLENCY THE GOVERNOR.

[A Royal Commission, consisting of Messrs. W. J. Dawkins (Chairman), Professor A. J. Perkins, and J. W. Wainwright, was appointed in January to inquire into and report upon the disparity between the prices paid by the consumer for dairy produce, the London parities of dairy produce, and the prices received by dairymen for milk and cream, the cause of such disparities, and the remedies therefor. The report is dated October 20th, 1933, and portion of it is quoted below.]

(Continued from Page 686, January issue.)

II. BUTTER.

A. THE NATIONAL SIGNIFICANCE OF BUTTER.

From the national viewpoint butter fills a three fold purpose. In the first place it is essential human food-stuff; secondly, it is rapidly becoming an export item of importance to South Australia; and thirdly it offers occupation for available family farm labor, particularly in times of low prices for staple farm crops. Its importance relatively to other true dairy products may be stressed as follows in terms of quantities of milk estimated to have been used in South Australia in the 1932-33 season:-

	Milk Used	
	Quantities	Percentages
	Galls.	%
Manufacture of butter	45,000,000	79.0
Human consumption, &c.	8,000,000	14.0
Manufacture of cheese	4,000,000	7.0
Approximate estimate of total milk produced	57,000,000	100.0

Recent progress achieved by the butter industry in South Australia may be gauged by the data that follow:-

Butter Manufactured.				
	In Factories.	On Farms.	Total.	Dairy Cows.
	Cwts.	Cwts.	Cwts.	Nos.
1926-27	88,000	32,000	120,000	127,000
1927-28	78,000	30,000	108,000	118,000
1928-29	73,000	28,000	101,000	109,000
1929-30	68,000	27,000	95,000	104,000
1930-31	87,000	29,000	116,000	110,000
1931-32	123,000	35,000	158,000	128,000
1932-33	150,000	45,000	195,000	149,000
Means—				
1926-30	76,750	29,250	106,000	114,500
1930-32	105,000	32,000	137,000	119,000
1932-33	150,000	45,000	195,000	149,000

It will be observed that much progress has been achieved during the course of the last two seasons. Relatively to 1929-30 butter production has been more than doubled and dairy cattle have increased by 45,000 head, or over 43 per cent. As will be seen later on, the question of farm-made butter is a vexed one with traders; in the meanwhile attention is drawn to the fact that although the quantity of butter made on farms has undoubtedly increased of recent years—from

27,000cwt. in 1929-30 to 45,000cwt. (estimate) in 1932-33 its proportional relation to total butter produced has actually declined, namely, from 29 per cent. of total butter made in 1929-30 to 23 per cent. in 1932-33 (estimate).

In view of all the circumstances it is very regrettable that general discontent should latterly have been rife among those dairymen whose business it is to separate milk and sell the cream thereof to butter manufacturers. All those who have attended public meetings at which dairy questions were discussed are aware of the intensity of this discontent, which indeed has been voiced by several witnesses who appeared before the Commission. The fundamental basis of this discontent is obviously the low values realised latterly for cans of cream, coupled with the almost ineradicable suspicion of suppliers of cream that in such transactions they did not usually get a fair deal.

B. DETERMINATION OF LOCAL BUTTER AND BUTTERFAT PRICES.

It is hardly necessary to stress the fact that the main factor behind the low local butterfat prices of recent years has been the progressive fall in London butter prices, which itself was brought about by an overstocked market under pressure of unprecedented world conditions. The position has, however, been complicated by other factors, and as there has been a good deal of misunderstanding among cream suppliers and others as to the relationship between butterfat prices, on the one hand, and wholesale and retail butter price, export bounties and London butter quotations, on the other, it is proposed to summarise the position in the following paragraphs:

1. *Normal Relative Value at Butter Wholesale Price.*—(a) When free play is allowed to economic factors, the home wholesale price of any commodity that is being produced in excess of home requirement, is more or less the price obtainable at the time on the best available importing market, less costs of delivery to that market, and plus or minus exchange differences operating between these two markets. Such, obviously, but for export bounties, would be the present position of butter in South Australia, with the additional limiting fact that Great Britain is her only possible importing market of any consequence; but even if South Australia had no exportable butter surplus, as happens fairly regularly at specified times of each year, the same factors would, nevertheless, continue to function, and exportable surpluses of other States of the Commonwealth would effectively check appreciable increase in South Australian butter prices above export parity, apart from such as would naturally arise from costs of transfer from one market to another.

(b) When, however, export and import markets respectively are separated by thousands of miles, as is Adelaide from London, then a new factor, which no prudent trader can afford to overlook, will come into action, namely, the relative stability of prices on the importing market at the time that manufacturing liabilities were being incurred in the exporting country. If at the time manufacturers should have reason to anticipate progressively rising overseas import prices wholesale prices of the exporting country would generally tend to rise slightly above corresponding strict export parity of the day; but if the reverse were the case, these wholesale prices would tend to lag behind strict export parity; and since in the latter case the financial success of the transaction would be in the balance, the lag of a falling import market would usually be proportionally greater than any corresponding price enhancement of a rising market.

(c) And, in the main, it is because ever since January, 1929, exporters have had to face progressively falling London butter prices that cream suppliers have from time to time been able to point to apparent discrepancies between local

(iii.) *Insurance*.—Insurance is assessed on a percentage of values and averaged 6d. per cwt. for the five-year period ending on June 30th, 1930; 5d. per cwt. for the three-year period ending June 30th, 1933.

(g) Hence, in rough summary, consignment sales to London would involve, under present conditions, costs varying from 22s. 10d. to 23s. 10d. per cwt., or 2.45d. to 2.55d. per lb.

For. c.i.f. sales corresponding costs would be 17s. 11d. per cwt., or 1.92d. per lb.

For f.o.b. sales, 6s. 10d. per cwt., or 0.73d. per lb.

2. *The Paterson Scheme*.—(a) *Constitution and Objective*.—In the above paragraph an attempt has been made to show in what fashion the Adelaide wholesale price of butter is linked up with London market prices. Ever since 1926, however, this normal relationship has been disturbed by the functioning of the Paterson scheme; and as this scheme is not well understood by those chiefly concerned, it is necessary to give it close consideration.

The Paterson scheme is a voluntary agreement between the butter manufacturers of Australia, excluding those of Western Australia, for the purpose of maintaining the Australian wholesale price of butter at a higher rate than its corresponding export parity. It is managed by a central controlling body known as the Australian Stabilisation Committee, upon which all States interested are represented. In addition, matters of purely local concern are left in the hands of State advisory committees. Complaints made before this Commission that South Australian producers were not represented on the Advisory Committee are met by the terms of the agreement which specifically provide that the power to create such a committee shall be vested in those directly responsible for the payment of the levies, namely, the local butter manufacturers. It follows that the absence of direct representatives of the cream suppliers of South Australia is due to the absence of co-operative factories in this State. It can be added, however, that, as in New South Wales, Victoria, and Queensland, 90 per cent. of the butter made is manufactured in co-operative factories, producers' interests are more than amply protected on the central controlling body, the majority of whose members are direct representatives of producers.

The prime objective of the agreement has been stated to be the raising of the Australian wholesale butter price above its corresponding export parity value; nor could such an objective have been achieved without a definitely binding understanding among the contracting States to the effect that the home market of each State should be left to the manufacturers of that State, and that no butter should be exported to another State unless there were a definite request for the same from manufacturers of that State. The results achieved have been remarkable, and are a tribute to the thoroughness with which a purely voluntary agreement has been observed by individuals with frequently divergent interests.

(b) *Method of Action*.—We have already seen that, under normal conditions, the Australian home wholesale price of butter is practically the same as the net price realisable by a manufacturer on the London market, or in other terms, its export parity. It follows that apart from statutory enactment, there is no way of increasing the home price of an exportable commodity, except by increasing the net returns of the exporter by means of an export bounty, the value per pound of which should be equal to the amount by which it was intended to raise the local wholesale price above export parity. For example, if the export parity of butter to-day were 8d., and if it were desired to raise the local wholesale price of butter by 3d. above parity, it would be necessary to provide a bounty of 3d. per lb., or 28s. per cwt. for all butter exported. If, in this matter, we assume the active co-operation of all butter manufacturers of the Commonwealth apart from those of Western Australia, the mere knowledge that such an export bounty were available to all manufacturers would, of itself, lead to the immediate

increase in the wholesale home consumption price of butter by an equal amount, that is to say, in the present example, from 8d. to 11d. per lb. In other words, since in the circumstances the mean net returns would be the same in either case, it would be quite immaterial to the manufacturer as to whether his butter were exported or whether it were sold on the home market, and tendencies towards competitive reductions in price would be reduced to a minimum, apart from questions of relative quantity and grade. Such, then, has been the policy that has been very successfully put into action by the Australian Stabilisation Committee.

But whilst it might be comparatively easy to secure theoretical agreement as to the advantages to producers of an export bounty on butter, it is quite another matter to give practical effect to the agreement on a purely voluntary basis, and without assistance from the public purse; and the original promoters of the Paterson scheme are to be congratulated on the ingenuity with which this difficulty has been met since 1926.

Towards this end a fixed yearly levy has been collected on all butter manufactured or processed in factories, and the aggregate value of these levies has generally sufficed to pay the requisite bounty on all butter exported from the Commonwealth, with the exception of Western Australia. It is sometimes loosely assumed that these levies have been made upon the producers, or cream suppliers. As this is very far from being the case, it is necessary to stress the fact that the fund from which the export bounties have been paid has been built up by contributions of the butter manufacturers of the Commonwealth, and subsequently recovered in butter sales made to consumers. It is, of course, true that in New South Wales, Victoria, and Queensland the great majority of the butter factories is under co-operative control, and that to that extent producers may be said to have assisted in building up the fund; but as part-owners of the factories only and not as producers. In South Australia, however, the trade is mainly in the hands of proprietary companies.

(c) *Benefit to Producers.*—The actual benefit derived by the dairyman from the Paterson scheme may be summarised as follows:—He will benefit to the extent that the wholesale price of butter in Australia has been raised above its corresponding export parity, less costs incurred by manufacturers to secure such a result, or, in other words, to the extent of the value of the export bounty per lb. of butter exported, less the value of the levy per lb. raised on all butter manufactured in order to pay this bounty. A concrete example will serve to make this position clear.

Let us assume that apart from bounties the London export parity of butter on the Adelaide market were 8d. per lb.; in the absence of bounties it would be on this figure that the price payable to dairymen for butterfat would be calculated, namely, 8d., less 2½d. for manufacturing costs, &c., multiplied by 1.18, or 6½d. per lb. of butterfat only.

If, again, we assume that as is the case at the present moment a Paterson bounty of 28s. per cwt., or 3d. per lb., were paid on all butter exported then the wholesale price of butter, which normally equals its export parity, namely, 8d. per lb. in this case, would be raised from 8d. to 11d. per lb.; but, in order to secure this result manufacturers would have contributed 1½d. per lb. on all butter manufactured in order to create the fund from which the export bounty could be paid. It follows that since the manufacturers must be compensated for their outlay in this direction the figure upon which the butterfat price would be calculated would be in this instance London export parity—8d.—plus the export bounty per pound—3d.—less manufacturers' advance of 1½d. on *all* butter manufactured. These calculations would give 9½d. instead of 8d., as the figure upon which the butterfat price would be calculated, namely 9½d., less 2½d., multiplied by 1.18, or 8d. per lb. of butterfat.

At this stage it is necessary to stress the fact that manufacturers and exporters have not benefited directly by a penny piece from the Paterson scheme; their aggregate net returns from overseas and home sales have been no greater than they would have been had there been no such scheme in existence. In fact, since manufacturers are obliged to provide levies on butter manufactured in advance of sales they can legitimately claim to have been out of pocket to the extent of interest due until such time as the value of the levies had been completely recouped by sales.

(d) *Varying Effectiveness of Paterson Levies.*—It has been shown above that the present benefit accruing to dairymen from the Paterson scheme was equivalent to 1½d. per lb. of butter manufactured only; in this connection it is necessary to recall that the scheme, although voluntary, is, apart from Western Australia, Commonwealth wide in its incidence, and that dairymen's Paterson benefit per lb. of butter manufactured has progressively declined under the influence of rapidly rising Commonwealth exports of butter; in other words, the "effectiveness" of the levy on butter manufactured has, from the dairymen's viewpoint, declined proportionally to the rise in the Commonwealth percentage of butter produced that has been exported abroad in any one year. These facts may be illustrated as follows:—If, as was the case between 1926 and 1929, one-third only of the butter produced in the Commonwealth were exported a levy of 2d. per lb. on manufactured butter would provide for a bounty of 6d. per lb. on all butter exported, and would raise the home wholesale price of butter by 6d. above export parity and the price paid to producers for butterfat by 4½d. per lb., or by 4d. on the basis of commercial butterfat. If, on the other hand, one-half of the butter produced in the Commonwealth were exported, as has happened since 1931-32, the same levy of 2d. per lb. on manufactured butter would provide for a bounty of 4d. per lb. only on *all* butter exported would raise the home wholesale price of butter by 4d., and the price paid to producers for butterfat by 2½d. per lb. only, or 2d. on the basis of commercial butterfat.

Data below show what has been the relationship of the Commonwealth export percentage to the Paterson scheme in each year since its inception and the corresponding benefit of the scheme to dairymen of Australia:—

Seasons.	Commonwealth Butter		Paterson Benefit to Dairymen		
	Exports as Percentages of Total Production.	Mean Levies per Lb. on Butter Manufactured.	Mean Export Bounties. Per Lb.	per Lb. of Butter Manufactured.	on Total Production.
	%	d.		d.	£
1926-27	30.40	1½	3½	2	2,104,425
1927-28	35.41	1½	3½	2	2,333,645
1928-29	35.34	1½	3½	2	2,415,693
1929-30	35.99	1½	4½	2½	3,426,965
1930-31	46.57	1½	3	1½	1,825,027
1931-32	51.58	1½	2½	1	1,638,896

Aggregate Paterson benefit to dairy industry (1926-1932) .. £13,744,651

NOTE A.—One half-penny has been added to mean export bounties in 1926-27 and 1927-28 seasons because in those two seasons corresponding amounts were refunded to cream suppliers.

NOTE B.—Aggregate benefit under the Paterson scheme has been calculated by multiplying the benefit per lb. by total butter production. This includes "farm" or "dairy" butter to which reference will be made later, on the grounds that farm butter, although it pays no levies, benefits with factory butter from the resulting rise in wholesale butter prices; but it is probable that farm butter does not usually secure the full benefit of the Paterson scheme, and hence figures given above have been to some extent over-stated.

From the above it will be seen that the aggregate benefit of the Paterson scheme to dairymen of the Commonwealth has been estimated at £13,750,000 between 1926-27 and 1931-32 inclusively, at the same time the value of this yearly aggregate has been gradually declining under the influence of increasing Commonwealth exports of butter.

Attention is drawn to the fact that whereas throughout the three seasons ending on June 30th, 1932, the mean levy on manufactured butter was uniformly 1½d. per lb., the dairyman's Paterson benefit during this period was on a descending scale in each successive season, namely, 2½d., 1½d., and 1d. per lb. of commercial butter respectively. We see here one of the factors that have of recent years led to apparent anomalies in butterfat prices, but which hitherto seems to have been overlooked. If, for purposes of illustration, it were assumed that London mean butter parity prices were the same in each one of these three seasons, say, 10d. per lb., then, other things being equal, including the levies on manufactured butter, the mean price of butterfat would have been 12½d. per lb. in 1929-30, 10½d. in 1930-31, and 10d. in 1931-32. Hence, notwithstanding the fact that the levies on manufactured butter were equal and the London parity prices were assumed to be equal in each year there would have been a difference of 2½d. between the price that could have been paid for butterfat in 1929-30 and that which could have been paid in 1931-32. Obviously, in this instance the controlling factor would have been the fact that in 1929-30 season one-third of the butter manufactured in the Commonwealth was exported and in 1931-32 more than half.

(d) *Paterson Scheme in Danger*.—At this stage it is necessary to stress the fact that the Paterson scheme, which over the past seven years has subsidised Commonwealth dairymen at the mean approximate rate of two and a quarter million per annum, is becoming increasingly difficult to carry on as a voluntary scheme. The position appears to have been caused by two main factors, namely—(1) progressive increase in the proportion of Commonwealth exports of manufactured butter and (2) progressive increase in Commonwealth output of "farm" or "dairy" butter; and it will be no exaggeration to add that in these times of deplorably low prices the disappearance of the Paterson scheme, unless countered by a suitable substitute, would very considerably reduce Australian exports of butter.

But, as has already been pointed out elsewhere, the Paterson scheme, although a purely voluntary organisation, functions, and has functioned well, throughout the Commonwealth with the exception of Western Australia; and even in the latter State a purely local Paterson scheme is at work. Hence, it would be idle to suggest individual State action with a view to saving it from extinction. The best that can be said in the matter is that the Commonwealth Government would confer an invaluable boon upon one of the foremost of Commonwealth rural industries if it could be induced to recognise the Paterson scheme by legal enactment *during the present economic crisis*. It is true that on the petition of representatives of the dairying industry of Australia the Commonwealth Government has already refused to take any such action, on the grounds, it is believed, that it could not give legal sanction to a private organisation, the main objective of which was to assist the industry by raising the price of butter to Australian consumers above London export parity. In the circumstances it seems somewhat anomalous that the Commonwealth Government should have offered as a substitute the complicated dried fruit legislation, which, in effect, would give rise to the very results that are apparently objected to in the Paterson scheme. Surely a successful scheme in being that has received the voluntary adherence of the dairying States of the Commonwealth should receive preference over an untried scheme that is not necessarily acceptable to all States alike, and particularly so when it can be said of the former that it has made no call upon the

public purse, and that it not only saved the dairying industry during seven successive years of gradually declining prices, but, in addition, rendered possible unparalleled expansion in production and in Commonwealth exports during the last three years. It can, indeed, be said that the Paterson scheme is in difficulties, not because it has failed, but because it has been too successful. If the scheme were definitely protected by Federal legislation *during the present economic crisis*, and subject to appropriate safeguards in the interests of consumers, the main difficulties could readily be dealt with; "farm" or "dairy" butter offered for sale would immediately become liable for the same levies as factory butter probably by means of a duty stamp; and the levy on all butter manufactured could be raised sufficiently to ensure to it the "effectiveness" of earlier years, which corresponded to a benefit to dairymen of about 2½d. per lb. of butterfat.

(c) *Paterson Statistical Data in South Australia*.—Data concerning levies collected on butter manufactured on the one hand and bounties paid on butter exported on the other, under the Paterson scheme in South Australia, are shown below for the seven and a half years ending on the 30th June, 1933:—

Paterson Scheme Data in South Australia.

Year.	Total Levies Collected.	Bounties Paid to South Australian Exporters.	Refunds to Suppliers.	Amounts Transferred to other States.
	£	£	£	£
1926	59,592	22,672	17,381	19,343
1927	50,283	10,678	14,613	23,000
1928	50,641	12,211	—	40,000
1929	51,286	14,144	—	33,000
1930	59,002	32,767	—	13,500
1931 (six months) . . .	27,358	13,428	—	22,000
1931-32	99,563	83,255	—	7,300
1932-33	125,636	123,711	—	2,000
Totals	523,361	312,866	31,994	160,143
Add refunds		31,994		
		344,860		
Add transfers		160,143		
Total outgoings		£505,003		

From the above it will be noted that during these seven and a half years the sum of £160,143, or over 30 per cent. of the total levies collected in South Australia, was transferred to other States. In this connection it must be pointed out that the Federal character of the Paterson scheme renders unavoidable such transfers of a proportion of the levies collected in States, such as South Australia, in which the home consumption percentage of butter produced in those States was relatively high, to States, such as Queensland, in which corresponding consumption percentages were low. In other words, although at the outset manufacturers advance the value of the Paterson scheme levies they recover the latter from the proceeds of subsequent sales, and, strictly speaking, the aggregate Commonwealth levies may be said to be paid by Commonwealth consumers for the benefit of Commonwealth dairymen; and since for the sake of convenience levies collected in any one State are, in the first instance, placed to the credit of that State it follows that some States will collect more than would be required for the payment of local export bounties—at the present moment New South Wales, South Australia, Tasmania, and (Western Australia)—whereas other States—at the present moment Queensland and Victoria—would collect less than would be required for the payment of export bounties in those States; hence, under the agreement States with surpluses transfer the latter to States with deficits.

It should be observed, however, that South Australia's exportable surplus is rapidly increasing, and with the continuance of favorable seasons there is reason to believe that this surplus will soon reach the Commonwealth mean surplus, which would imply a cessation of transfers of South Australian money to the wealthier States.

(f) *Commonwealth Paterson Statistical Data.*—Comprehensive data concerning the Commonwealth position of the Paterson scheme are shown below:—

Commonwealth Paterson Scheme.

	Total Levies Collected in Australia.	Pates of Levy.	Total Amounts of Bounties Paid to Australian Exporters.	Rates of Bounties.	Refunded to Australian Cream Suppliers.
	£	d.	£	d.	£
1926	1,451,804	1½	990,248	3	422,829
1927	1,441,054	1½	1,046,941	3	417,088
1928	1,709,276	1½	1,689,546	3, 4	—
1929	2,115,582	1½	2,119,193	4½	—

Add refunds			839,917		
Total outgoings			12,526,650		

3. *Supplementary or Equalisation Scheme.*—The Commonwealth Paterson Scheme has not, however, been the only "scheme" that has of recent years influenced butter prices to the advantage of producers on the South Australian market; in addition, a purely South Australian scheme, known as the "Supplementary" or "Equalisation" scheme, has been functioning since September 23rd, 1929, and it is necessary to give it brief consideration.

It has already been stressed that ever since Australia entered the ranks of butter exporters the home wholesale price of butter has necessarily been determined upon a basis of London parity, and that since the value of the Paterson Export Bounty has led to a corresponding increase in the home wholesale price above London parity, to all intents and purposes the Paterson scheme cannot be said to have disturbed the dependence of local prices upon London prices. On the other hand, London prices vary from time to time, and for the convenience of trade and the avoidance of wasteful competition, it has been customary for manufacturers to determine on each Monday what shall be for the current week the home wholesale price of butter on the basis of the London parity of the day. This arbitrary fixation of a price for a definite number of days on the export parity of a single day, however useful from a local trading point of view, must obviously lead to disparity between Australian and London prices, according as the latter rose or fell during the course of the week. The effects of these disparities were, however, of little consequence in South Australia, so long as our exports of butter remained more or less negligible. But as soon as South Australian exports began to assume appreciable proportions difficulties developed. Manufacturers tended to separate out into two sections, namely, those who in the main catered for the home market on the one hand, and those who in the main were exporters, on the other; and the latter, who by the payment of levies had, in common with others, assisted to maintain local prices above London parity, claimed rightly enough that factory-door net returns from exported butter should be no less than corresponding returns from butter sold on the local market. Unfortunately, too, during these years of expanding exports, traders have been faced with progressively falling London prices, and it follows that weekly disparities between London and Adelaide have usually told against

exporters. Another difficulty of the position, of which both sections were well aware, was that the dwindling effectiveness of Paterson levies had fallen so low that it was highly doubtful that current prices paid for butterfat would suffice to maintain the rate of production upon which both sections of the trade depended. It is to difficulties such as these that the supplementary scheme may be said to have owed its genesis.

The mechanism of the scheme is substantially that of the Paterson Scheme, that is to say, levies are made on all butter manufactured, and bounties are paid on exports from the fund created and maintained by these levies. The main differences between the two schemes are:—(1) That whereas under the Paterson Scheme the rates of levies and bounties are fairly constant throughout a twelvemonth, under the supplementary scheme they vary from time to time, according to the requirements of the position; and (2) that owing to the fact that the supplementary scheme is a purely South Australian scheme, the effectiveness of its levies, and consequently its benefit to producers, is far greater than that of the Commonwealth Paterson Scheme. The rates of levies and bounties under this scheme since its initiation have been as follows:—

	Levies. d. per lb.	Bounties. d. per lb.	Benefit to Producers. d. per lb.
1929-30	$\frac{1}{4}$	$1\frac{1}{2}$	$1\frac{1}{2}$
1930-31	$\frac{1}{4}$ to $\frac{1}{2}$	$\frac{1}{4}$ to 2	$\frac{1}{4}$ to $1\frac{1}{2}$
1931-32	$\frac{1}{4}$ to $\frac{3}{8}$	$\frac{1}{4}$ to $2\frac{3}{8}$	Nil to $1\frac{1}{2}$
1932-33	$1/16$ to 1	$\frac{1}{4}$ to $2\frac{1}{2}$	$1/16$ to $1\frac{1}{2}$

It should be added that from time to time the trade has by agreement suspended both levies and bounties under the supplementary scheme.

The mode of action of the supplementary scheme on a falling market may be illustrated by the following example:—

Let us suppose that on a given Monday the local wholesale price of butter had been fixed upon the basis of 70s. per cwt., f.o.b., i.e., 9 $\frac{1}{2}$ d. per lb., exclusive of supplementary bounty but inclusive of 28s. per cwt. Paterson Bounty. On this basis the price payable for butterfat would be 8 $\frac{1}{2}$ d. per lb.

If, now, we suppose further that on the Monday following, f.o.b. prices appeared to be in the neighborhood of 65s., exporters would claim that the local butter price should be lowered, otherwise their sales would be made at a disadvantage relatively to local sales. On the other hand, the trade generally would be averse to a reduction in the price of butterfat, which already was abnormally low. In this connection the difficulty would be overcome by providing a bounty under the supplementary scheme, which, after deduction of the levy, would leave to the exporter an additional $\frac{1}{2}$ d. per lb., and place him on a level footing with local sellers. And this accordingly has been done from time to time.

Similarly, should the market advance instead of receding, matters could be adjusted between exporters and local sellers by reducing the supplementary bounty to a corresponding degree.

But although the original objective of the supplementary scheme was to equalise matters between exporters and local sellers, it has not been without other advantages. In the first place, it should be noted that as soon as an additional export bounty is provided for, the local wholesale price responds by an equivalent increase, and the producer benefits to the extent of the difference between the new bounty on the one hand and the new levy on the other. But, apart from this aspect of the question, in the words of Mr. Harding Browne, as soon as the trade became familiar with the supplementary scheme they realised that it had many other possibilities in it. Hence, to some extent, and particularly in times of local scarcity, the supplementary scheme has been used to maintain local butter prices above those of other States. Such an action would not, of course, have been possible except for the binding agreement between all manufacturers, traders, and agents of the Commonwealth to the effect that in each State local manufacturers

should have a free field within their own territory, and that no butter should be exported to another State except at the demand and under the supervision of the local State Advisory Committee.

Further, in addition to levies on butter manufactured in the State, it has been customary to impose special levies on all butter imported into South Australia because of temporary local scarcity. Such action was found necessary because at such times local prices were usually maintained at a higher level than the prices of other States, and it became necessary to equalise matters between the two. These special levies have hitherto varied between $\frac{1}{4}$ d. and $1\frac{1}{4}$ d. per lb.

One example of the effectiveness of the supplementary scheme in this direction will be given from the evidence of Mr. A. G. Taylor. This concerns two f.o.b. sales, one of which took place on November 1st, 1932, at 100s. per cwt., and the other on March 14th, 1933, at 72s. per cwt. Transactions involved were as follows :—

	November 1st, 1932.		March 14th, 1933.	
	s. d.	s. d.	s. d.	s. d.
F.O.B. price per cwt.		100 0		72 0
Less Adelaide charges		7 0		7 0
		93 0		65 0
Plus Paterson bounty	28 0		28 0	
Supplementary bounty	2 8	30 8	30 8	58 8
		123 8		123 8
Corresponding wholesale butter price ...		1 1 $\frac{1}{4}$		1 1 $\frac{1}{4}$
Less Manufacturing charges	0 2 $\frac{1}{2}$		0 2 $\frac{1}{2}$	
Paterson levy	0 1 $\frac{3}{4}$		0 1 $\frac{3}{4}$	
Supplementary levy	0 0 $\frac{3}{4}$	0 4 $\frac{7}{16}$	0 0 $\frac{1}{16}$	0 5 $\frac{3}{16}$
		0 8 $\frac{13}{16}$		0 8 $\frac{1}{16}$
		$\times 1.18$		$\times 1.18$
		— 10 $\frac{1}{2}$ d.		— 9 $\frac{1}{2}$ d.
Butterfat price				

It will be observed that although on March 14th, 1933, the f.o.b. price was as low as 72s., it was possible, by means of a supplementary export bounty of 30s. 8d. per cwt., to maintain the local wholesale price of butter at the same level as on November 1st, 1932, namely, 1s. $1\frac{1}{4}$ d. per lb., at a time when the f.o.b. value was as high as 100s. per cwt. The price paid for butterfat, however, had to fall from $10\frac{1}{2}$ d. to $9\frac{1}{2}$ d., owing to the relatively high level of 15/16d. per lb. Had it not been for the supplementary bounty the price payable for butterfat on the 1st March, 1933, would have been $6\frac{3}{4}$ d. per lb. instead of $9\frac{1}{2}$ d.

Those responsible for inaugurating and successfully working the supplementary scheme are to be congratulated upon their efforts, and in view of the apparently precarious position of the Commonwealth Paterson Scheme, your Commissioners desire to stress the fact that should the latter eventually close down, South Australia has, in the supplementary scheme, adequate machinery for a purely State organisation, which, under present guidance and management, could effectively replace the Paterson Scheme, provided that South Australia could continue to be protected against an inflow of outside butter. In such circumstances your Commissioners would respectfully commend the supplementary scheme for Government assistance and protection until such time as the price of butter should reach more normal levels.

4. "Farm" or "Dairy" Butter.—In the present report occasional reference has already been made to the supposed injurious influence of "farm" or "dairy" butter upon the Paterson Scheme. It is necessary, therefore, to examine this question in close detail.

In the tabulated statement that follows the relationship of dairy butter to total production in each of the States concerned has been shown for a period of six years ending on June 30th, 1932.

Seasons.	New South Wales.			Victoria.			Queensland.			South Australia.			Tasmania.			Total of the Five States.		
	Quantities Made.	Percentage of Total Production.	Quantities Made.	Quantities Made.	Percentage of Total Production.	Quantities Made.	Quantities Made.	Percentage of Total Production.	Quantities Made.	Quantities Made.	Percentage of Total Production.	Quantities Made.	Quantities Made.	Percentage of Total Production.	Quantities Made.	Quantities Made.	Percentage of Total Production.	
	Cwts.	%	Cwts.	Cwts.	%	Cwts.	Cwts.	%	Cwts.	Cwts.	%	Cwts.	Cwts.	%	Cwts.	Cwts.	%	
926-27	42,891	5.01	34,708	20,962	4.57	31,778	26.53	29.24	15,747	146,086	6.58							
927-28	43,647	4.85	32,074	22,989	3.57	30,307	27.97	31.61	18,387	147,404	5.99							
928-29	40,274	4.73	30,933	23,734	3.45	28,204	27.92	27.19	17,952	141,097	5.55							
929-30	37,572	4.04	30,980	24,044	3.42	27,974	29.04	24.14	18,294	138,864	5.31							
930-31	43,837	4.34	33,581	25,210	2.95	29,156	25.19	22.97	20,108	154,892	4.98							
931-32	48,209	4.36	37,054	26,449	3.02	34,235	21.71	25.86	21,848	167,795	4.93							

From the above data the following points should be noted:—

(i.) In the matter of "farm" butter the five Paterson Scheme States separate into two sections, namely:—

(a) The larger butter-producing States—New South Wales, Victoria, and Queensland—in which during the six seasons under consideration the percentage of "farm" butter made has varied from 3 per cent. to 5 per cent. of total butter produced in any one season; and

(b) The smaller butter-producing States—South Australia and Tasmania—in which over the same period the percentage of "farm" butter made has varied from 21 per cent. to 31 per cent. of total production.

(ii.) But owing to the vast total quantities of butter produced in the three larger States, namely, on the average, 2,528,294cwts. per annum, relatively to corresponding production in the two smaller States, namely, on the average, 187,470cwts. per annum only, the high percentage of "farm" butter made in the latter has not affected the mean percentage of the five States very appreciably. The latter percentage varied from 5 per cent. to 6½ per cent. only.

(iii.) It is true that the quantities of "farm" butter made in all States have shown a tendency to increase during the six seasons under consideration, but particularly so in 1930-31 and 1931-32, and it is stated in the trade that when the figures become available the increases will be found to be more striking in 1932-33. But, on the other hand, these increases in "farm" butter have not kept pace with total production increases, and the percentages have accordingly declined.

WALLAROO-MOUNT LYELL FERTILISERS LTD.

Wallaroo and Port Adelaide.

From the above we may conclude that the high proportion of "farm" butter made in South Australia and Tasmania has not injured the Paterson Scheme to the extent that it has usually been assumed to have done. It must be remembered that there always has been, and always will be, a limited but perfectly legitimate demand for well-made "farm" butter; and that levies on sales of this type of butter could not be expected until such time as the Paterson Scheme received Commonwealth legal sanction. Similarly, in South Australia, and probably in all the States, many farmers in outlying districts are unable to market their cream to advantage except as farm butter, which, again, will escape Paterson levies. During the six seasons under consideration the mean percentage of farm butter in the five States was 5.48 per cent., but for the three large producing States 3.95 per cent. only; we may assume, therefore, that 4 per cent. of total butter as farm butter would make ample provision for legitimate escapees from Paterson levies; and 1.48 per cent. of total production would, therefore, represent the extent of the damage done to the Paterson Scheme by some dairymen in South Australia and Tasmania. The monetary value of this damage can be assessed as follows:—1.48 per cent. of total butter production of the five States in the six seasons had a mean value of 40,290 cwt. of butter per annum, on which a sum of £32,904 per annum in levies would have been lost to the Paterson Scheme. On the other hand, had these levies been collected and distributed in the form of export bounties their influence on mean exports of 1,357,882 cwt. per annum would not have exceeded 5d. per cwt., that is to say, an amount which could not have had even fractional influence on the local price of butterfat per lb., and the latter, after all, was the main objective of the Paterson Scheme.

But, although the relative insignificance of their dairy production obviously absolved South Australia and Tasmania from the accusation of having done appreciable damage to the Paterson Scheme, it was surely not to the credit of the dairymen of these two States that at a time when brother dairymen in other States were straining every nerve to raise the local price of butter above its calamitous London parity equivalent, 20 per cent. to 30 per cent. of the former should not have hesitated to take full advantage of the results secured, whilst they did not contribute a penny piece towards the latter. The matter might, perhaps, have been overlooked had the butter made been commercially possible; the great bulk of it, however, is usually saturated with butter milk, badly worked, of doubtful soundness, and manufactured and handled under unhygienic conditions. Most country storekeepers think themselves obliged to accept farm butter, in common with eggs, in payment for their own goods; they sell what they can locally, and finally dispose of the remnant for whatever it will fetch to the factories, in which it will be deodorised and reprocessed, and subsequently disposed of as a low-grade butter.

In the above connection your Commissioners wish to stress the fact that in the interests of public health stringent regulations are enforced relative to the handling and manufacture of butter in factories, and relative to the ultimate composition of that butter; and, in view of the fact that 20 per cent. to 30 per cent. of the butter produced in the State is now usually badly-made farm butter, they recommend that, for the protection of public health, the premises of all farms upon which butter is made for sale or exchange shall be subject to similar measures of inspection and similar regulations, including those prescribing the recognised standards for saleable butter.

Attention is also drawn to the fact that on the 3rd day of July last a special resolution was adopted by South Australian butter factories to the effect that from that date they undertook that they would no longer reprocess farm butter; and this may be accounted as the first shot in the campaign against unwanted farm butter. It may be of interest to note in this connection that during the 12 months ending on the 30th June, 1933, about 3,678 cwt. of farm butter was reprocessed in South Australian butter factories.

5. *Critique of Cream Payments.*—(i.) *Usual Complaints of Suppliers.*—The grave suspicions to which these transactions have given rise in the minds of suppliers have already been hinted at earlier in this report; and, as in such matters, it is usually the unknown or the nebulously perceived which is generally responsible for these regrettable misunderstandings, it seems worth while to explore the position from every possible angle, and, from an entirely impartial outlook, state the facts in the frankest manner possible. If this be well done, it is hoped that, if not all grounds for suspicion, at all events the grosser amongst them may be dispelled for all time.

A very common complaint is to the effect that the cream supplier's wife was able to make from a can of cream more commercial butter than should have been possible on the basis of the number of pounds of butterfat paid for by a factory manager from a corresponding can of cream; and to cap the position, the cream supplier's wife had been able to realise more money than the factory manager was willing to pay. This, of course, is the genesis of farm butter.

Unfortunately, we have here one of those problems that involve the difficulties of proving a negative. Moreover, the facts as stated by the cream supplier might be substantially correct without, however, involving any moral delinquency on the part of the factory manager or of his employees. Nevertheless, it must be stressed that in most cases of this character the cream supplier and his wife are not necessarily the best possible judges of what constituted two absolutely even cans of cream; and particularly not if the attempt were made to divide into two equal parts a specially thick can of cream. But in a general way it may be admitted that the farmer's wife will make more butter from a given quantity of butterfat than she is legally entitled to do. Her butter will generally be insufficiently worked; it will contain too much butter milk, and therefore more moisture than the law allows, and her hand might be on the heavy side when salting the butter.

On the other hand, it is readily understandable that the farmer's wife should be able to command a higher price for butter—the finished product—than the factory manager could afford to pay for butterfat—the raw material. But to clamor for similarity of payment would be as reasonable as the claim of a wheat farmer to be paid for wheat on the same basis as bread.

Another common complaint is to the effect that when dissatisfied cream suppliers take their cream to another factory they can usually depend upon improved money returns for a few weeks; but that thereafter returns fall back to the old level. In this connection the sinister inference is usually drawn that the old clients of the factory are made to pay for the welcome given to the new clients; in other words, the robbing of Peter to pay Paul.

The preliminary overpayment of new clients is too common and well-established a fact to be denied; indeed, as will be shown in the sequel, it is one of the natural consequences of deliberate suppression of price competition; but, as between factory and cream supplier, it is no more immoral or commercially undesirable than the well-known practice of some shopkeepers of throwing in with every purchase some unconsidered trifle, with a view to increase in business. The main objection, if any, is that it tends to deceive the supplier as to the true value of his cream, and eventually to confirm his opinion that in the matter of honesty there is not much to choose between factory managers.

But whilst in certain circumstances slight preliminary overpayment might be commercially defensible, those who imagine that it cannot be done except at the expense of other unsuspecting clients can have but the haziest notion of commercial transactions; nor can they realise the perilous position of the factory proprietor who deliberately instructed his employees to tamper with payments to old clients in order to provide a bonus for new ones.

Similar in character are the complaints that (a) cream is graded below value; (b) butterfat tests are systematically inaccurate; (c) net cream weights are in correct; (d) butterfat prices do not correspond to overseas parity, or even to local retail prices, &c. In effect, cream suppliers appear to believe that every possible advantage is taken of them in order to withhold portion of the money that is their due. And, ludicrous though most of these complaints are, it cannot be denied that by ill-considered actions in the past manufacturers themselves have been largely responsible for the atmosphere of suspicion from which these complaints have materialised. Very briefly, they may be dealt with as follows:—

(a) It is against the probabilities of the case that cream should have been graded below its value, except possibly in error. A far more general occurrence is the grading of cream above its value, due to the manufacturer's fear of losing clients. This is one of the factors behind the relatively low quality of South Australian butter. How manufacturers appear able to pay the same price for choicest and second grade cream will be discussed later on; obviously it is one of those factors that help to confirm the suspicion of suspicious minds.

(b) All factories employ certificated testers, whose certificates would be cancelled should they be detected in entering wrong tests. It is absurd to suppose that testers would risk their means of livelihood by deliberately reducing tests, or that their employers would risk their trade reputations by asking them to do so. At the special request of manufacturers, the Department of Agriculture is now preparing special regulations, which stipulate that numbered samples of all cream tested in any one day shall be kept back for 24 hours after the day of testing. Hence, any inspector coming into a factory will be in a position to check all tests of the immediately preceding day. Provision is also being made that payment to cream suppliers shall be strictly based upon the sheets of the cream tests.

(c) In the matter of irregular net cream weights, suppliers are usually in a position to do their own checking.

(d) The relationship of butter fat prices to London butter prices has already been dealt with in detail earlier in this report. As to local retail prices it can be said that a charge of 3d. per lb. is usually made by manufacturers for costs of delivery and putting the butter into prints, and that the retailer usually claims for expenses and profits 2d. per lb. above factory print prices. Cut prices, which are common in the retail trade, frequently tend to confuse the issues.

(ii.) *The Position of the Factories.*—The position of the factories in the matter is admittedly difficult, their opening offence is that in this State they are for the most part proprietary concerns, and as such suspect to cream suppliers whom it is their natural aim in life to conciliate: the majority of these factories has spared no expense to render itself technically efficient, in the matter of premises, equipment, and personnel, all are acutely aware that their very existence, let alone profits, is apart from efficiency, dependent upon continuously adequate turnover, and that this turnover is at the mercy of an independent army of cream suppliers, who delivers it up in weekly or bi-weekly dribblets of varying degrees of quality. The main function of the factory is therefore to attract to it as much cream as it can possibly handle and adequately market. Was it conceivable therefore that these factories whose existence was dependent upon continuity of supply should of set purpose tamper with the meagre weekly payments to those whom it was their ambition to retain indefinitely on their pay rolls? And yet such appears to be the general impression among cream suppliers, and the only consolation in the matter that the factories may take to themselves is that this impression embraces them, one and all, to an equal degree, and that after all factories are quite as essential to the wellbeing of cream suppliers, as the latter are essential to the wellbeing of factories.

Examples are not wanting to show that the factories have fully realised that ability to balance their ledgers was more or less related to ability in their clients to continue in active occupation of their holdings, but unfortunately, any overt act on their part in this direction has always been open to misconception. The factories, for instance, appreciated to the full the disastrous influence of declining world prices on the future prospects of their clients, and entered zealously into the Paterson scheme, and provided the not inconsiderable sums from which the export bounties were paid, but when in the course of time they made it known that before passing on the advantage of the export bounty to the producer, they were compelled to deduct therefrom the value of the levies, which they themselves had provided, they were immediately accused of keeping back from the producer something to which they had no legal right.

The pertinacity of factories in paying choicest price for inferior cream is but another example of the value which they place on the goodwill of the least desirable of their customers.

The fleets of motor trucks which scour country roads and by-ways, and which for a song, and at times for nothing, pick up partially filled cans of cream from the farm gate post, are supposed to be rendering a service to suppliers of cream, and yet they are viewed with the gravest suspicion by the latter. These costly conveyances, say these ungrateful clients, are run from unearned profits wrung out of the unfortunate cream suppliers. As a matter of fact, each motor truck is a marauding unit, with entirely benevolent intentions towards cream suppliers, but intent upon snatching disgruntled suppliers from rival factories. But since all factories follow the same line of policy, costs involved are pure waste of money, and as such cream suppliers, for once, have legitimate grounds of complaints.

This leads us to the point that many of the actions of the factories would appear to lend color to the popular view that more money was made from butter-making than was always apparent from a study of balance-sheets, hence the necessity of giving close consideration to this point.

(iii.) *Factory Revenues and Costs.*—There is a popular misconception among dairymen to the effect that factory manufacturing charges should have been reduced proportionally to the fall in prices of butter and butterfat, it has even been suggested that economies on lines of the Premiers' Plan should have been applied to the industry. It is overlooked, however, that the economic position of a large industrial undertaking is very different from that of a rural undertaking owned and managed by a farmer-proprietor. Such an undertaking, whether owned co-operatively or a proprietary concern, is in effect a national undertaking outweighing in national importance and service many hundreds of cream suppliers. It has been built up at great cost for the special purpose, in this instance, of providing adequate marketing facilities for the dairying industry of the State. The bulk of the capital invested in an undertaking of this kind is usually represented by borrowed money, or share capital in one form or another, and interest on this money must be found whether the price of butter be high or low. Similarly, the payment of a competent technical staff, provision for general working expenses, the accumulation of reserves towards replacement of wasting assets, and such improvements as changing conditions render necessary, must all be met each year, and cannot be accommodated to the rise or fall of the prices of raw material. Moreover, market risks are all the greater in periods of depression and falling markets, and in such times the only sane attitude for those in control of large industrial undertakings should, both in their own interests and those of the community, be towards maintaining them intact for better use in better times, nor can this be done by under-charging for services rendered. Hence, what we have to consider in the above connection is not so much as to

whether recent factory manufacturing charges can be considered reasonable in relation to current butter and butterfat prices, but rather whether profits disclosed in balance-sheets have been unreasonably large or not.

Balance-sheets of the transactions of several of these proprietary companies have been examined, and, as far as could be ascertained, the profits of recent years have not been excessive. But, unfortunately, these companies are not as a rule exclusively butter manufacturers—they may be produce merchants, general merchants, &c., as well—and whereas the individual position of these companies will no doubt be accurately reflected in their respective yearly balance-sheets, it is rarely possible to segregate costs and transactions that concern butter to the exclusion of other activities of the companies. This aspect of the matter acquires added importance when “costing” inquiries become necessary. Thus a factory proprietor assured the Commission that if the costly practice of picking up farmers’ cream by means of motor vehicles were abandoned by mutual agreement, or prohibited by law, it would then be possible to raise the price of butterfat by at least $\frac{1}{2}$ d. per lb.; in other words, that in his opinion, the present so-called “manufacturing costs” of 2 $\frac{1}{2}$ d. per lb. were at least $\frac{1}{2}$ d. too high, due to unwarranted competitive service to the farmer, who was well able to do the work himself. Unfortunately, in a matter such as this, the Commission is not in a position to decide whether even 2d. per lb. was a fair estimate of costs of manufacture, because neither records nor accounts have been kept in such a manner as to render accurate “costing” possible. Hence, since some measure of supervision in this direction seems unavoidable, if only with a view to allaying unwarranted suspicion, your Commissioners recommend that the accounts of each butter factory be kept in such a manner that the following information is separately recorded:—

- (1) The expenditure involved in the delivery of cream and/or butter and/or milk at the factory door.
- (2) The charges made to cream suppliers and others to recoup the expenditure thus incurred.
- (3) The expenditure involved in manufacture, buying, and selling of cream, milk, and butter.
- (4) Expenditure incurred in the delivery of butter to buyers, stores, &c., for local sale.
- (5) Expenditure incurred in consignment and delivery of butter for sale abroad.

(iv.) *Prices Paid for Butterfat.*—The manner in which local wholesale prices of butter are connected up with London butter prices has already been shown in detail; similarly, the relationship of butterfat prices to the above prices has also been stated, but not critically examined.

It should be stated here that these prices—wholesale butter price and butterfat price—are determined weekly at a special meeting of manufacturers, and until comparatively recently these prices have been based upon f.o.b. or c.i.f. & c. quotations known at the time to those attending the meeting. Early in the present year, however, a tendency appeared in some quarters to sell Australian butter in London on forward f.o.b. quotations; eventually the Australian Export Control Board came to the conclusion that transactions of this kind had a dangerously demoralising influence on a persistently falling market, and prohibited future overseas sales of Australian butter at prices below f.o.b. or c.i.f. & c. limits to be supplied weekly to all States by the Board. In this connection South Australia has been allowed the doubtful privilege of selling butter 2s. below the limit of the Export Control Board, presumably in recognition of the lower average quality of our butter.

In the discussion that follows it will be simpler to consider butterfat prices in relation to f.o.b. quotations. Two examples of this relationship are given below, namely, one for the week commencing August 14th, 1933, and the other for the week commencing September 17th, 1933:—

	Week Commencing August, 14th, 1933.		Week Commencing September 17th, 1933.	
	Per Cwt. s. d.	Per Lb. d.	Per Cwt. s. d.	Per Lb. d.
F.O.B. price	96 6	10.34	105 0	11.25
Less local export costs . .	7 0	0.75	7 0	0.75
	89 6	9.59	98 0	10.50
Plus Paterson bounty . . .	28 0	3.00	28 0	3.00
Plus supplementary bounty	15 6	1.66	11 8	1.25
Adelaide wholesale price .	133 0	14.25	137 8	14.75
Less manufacturer's charges	23 4	2.50	23 4	2.50
	109 8	11.75	114 4	12.25
Less Paterson levy	16 4	1.75	16 4	1.75
	93 4	10.00	98 0	10.50
Less supplementary levy . .	7 7	0.81	8 9	0.94
Multiply by 1.18	85 9	9.19	89 3	9.56
Butterfat price	101 2½	10.84	105 3¼	11.28

Before opening a general discussion on the above statement the atmosphere of suspicion that surrounds all dairy questions renders it advisable to repeat here that in this statement the levies deducted from the wholesale price of butter represented moneys especially advanced by manufacturers for the purpose of lifting the local price of butter above export parity; hence, it follows that dairymen cannot be credited with the full value of the increase above parity, which corresponded to the value of the export bounties, but only with the difference between bounties and levies respectively. It is worth noting, too, that had there been no Paterson and supplementary schemes in operation the butterfat price in the week beginning August 14th, 1933, would have been 8½d. per lb. only instead of 10¾d., and in the week beginning September 17th, 1933, 9½d. per lb. instead of 11½d.

If levies and export bounties be omitted from consideration, the determination of the weekly price of butterfat becomes comparatively easy. To this end costs incurred between the factory and the ship, say, ¾d. per lb., are first deducted from the f.o.b. price of butter; a corresponding deduction is then made for the so-called costs of manufacture, say, 2½d. per lb.; finally the remnant of these two deductions should be multiplied by 1.18, and the result would be the butterfat prices for the week.

Before examining in detail the chief items that enter into these calculations, it is necessary to stress the fact that the main purpose behind these calculations runs counter to a very important economic factor, namely, trade competition, which in effect it attempts to suppress by fixing the maximum price that shall be paid for butterfat in any one week. It is true that these prices may, and frequently do, vary from week to week, but in each week they are determined on the same rigid lines, which admit of no price competition between manufacturers. Hence we appear to have here an example of price fixation by individuals interested in one side only of the bargain, and since there must obviously be varying degrees of business and technical efficiency among manufacturers forming party to this price fixation agreement, it follows that a price that leaves a normal profit

to the least efficient must in certain circumstances leave an abnormal one to the most efficient. And in the meanwhile the less efficient are protected by the fixed price, and the cream supplier and the community as a whole lose the advantages of keen competition among efficient trade rivals.

But if price fixation has succeeded in stifling the healthiest and most effective form of trade competition, namely, price competition, it cannot be said to have displaced competition altogether; it has merely driven the latter underground. It can indeed be said that it is to the artificial fixing of the price of butterfat that we owe, indirectly if not directly, such measures as the ingratiating motor service between factory and farm, deceptive initial over-payments of disgruntled suppliers of rival factories, deliberate overgrading of inferior cream, refusal to distinguish in the matter of payments between good and bad cream, the tendency to pay for cream on a flat rate, whether delivered at the seaboard or at inland centres; in fact, all those measures by means of which it was hoped to gain favor with suppliers and trade advantages over rivals. But, unfortunately, all such actions have been perversely misconstrued by suppliers, who "feared the Greeks even when they came with gifts in their hands"; and hence, both directly and indirectly, the regrettable atmosphere of suspicion and distrust in which the industry has been immersed of late years can be traced back to injudicious price fixation of butterfat and the suppression of price competition.

It is the opinion of your Commissioners that price fixation is one of those measures which should be availed of only when none other appears to be available—they have recommended it in corresponding circumstances elsewhere in this report—but even then it is apt to work against the best interests of the community if left in the hands of interested parties. In the instance under consideration your Commissioners believe that price fixation is justifiable in the matter of the wholesale price of butter, because no other adequate means of adjusting the conflicting interests of exporters and home suppliers is apparent. Moreover, the fact that the price eventually determined upon is inevitably the result of a compromise between divergent interests is sufficient guarantee that the community as a whole is not likely to suffer thereby. There does not, however, appear to be a sufficient reason why the price of butterfat should be fixed. If the market were free, as it undoubtedly should be in the interests of producers, the same calculations to arrive at its price would no doubt be made, but not necessarily with the same results. The more efficient among the manufacturers would come to realise that the underground work of the past was no longer good business; and that the relative magnitude of their turnover would depend exclusively upon their ability to outbid their rivals in prices offered for butterfat. And eventually the 2½d. per lb. which under present conditions is claimed and secured by all and sundry for so-called manufacturing costs would gradually recede until it reached its true mean commercial value under efficient methods of management. On the other hand, the outlook of the less efficient would not necessarily be hopeless. They would probably find in keen price competition the necessary stimulus to improved technique, which eventually should enable them to compete on level terms with their more advanced rivals. The producers' gain in the matter should be appreciable increase in the price of butterfat under corresponding conditions, provided that the market could be kept open and free.

In the meanwhile, however, and in the absence of a free market for butterfat, it becomes necessary to examine closely the fairness of the formula upon which the price of butterfat has hitherto been fixed. At this stage it is convenient to reply to the introductory portion of Appendix VI., in which Mr. Harding Browne sets out very clearly manufacturers' objections to "making public their commercial calculations." In summary they claim that these calculations are intricate and liable to vary from day to day, and therefore open to misinterpretation by the uninitiated. They seem to claim, too, that no more than any other body of merchants should

they be compelled to reveal in detail the calculations upon which they base the price of their raw material. In the opinion of your Commissioners arguments such as these are perfectly sound and legitimate, provided that the market of the raw material were free and subject to price competition; but when this is notoriously not the case, not only cream suppliers, but the community as a whole, has a right to know exactly what takes place when such prices are fixed, and it must be acknowledged that manufacturers have not hesitated to lay all their cards on the table in so far as this question is concerned.

(a) *Local Costs Between Factory and Ship.*—These local costs represent the first item to be deducted from the f.o.b. price, and one usually estimated at 7s. per cwt., or 3d. per lb. The details vary slightly from firm to firm, and from time to time, but the following may be accepted as representative of present-day conditions (September, 1933):—

	Per Cwt.
	s. d.
Two export cases at 1s. 6½d.	3 1½
Export levy, 1/30d. per lb.	0 3½
Grading, carting, and wharfage	2 6
Brokerage	0 11½
	6 11

In some statements on this subject supplied to the Commission, freight from country stations had been included. Such a charge does not appear to be a legitimate debit against export charges; it should, in fact, have been recovered in reduced price for butterfat by inland factories.

(b) *"Manufacturing Costs."*—The above term is stated in Appendix VI. to be a misnomer; and well it might be, and yet it must have been coined by the manufacturers themselves. Actually this charge, which has been standardised at 2½d. per lb., includes cost of manufacture, market risks, and the manufacturer's profit. In addition, manufacturers make a charge of ¾d. per lb., or 7s. per cwt., for putting the butter into 1lb. prints, and delivering it to the retailers, that is to say, exactly as much as it costs to put butter aboard at the Outer Harbor. If the manufacturers agreed amongst themselves to call for a contractor to deliver their butter, and sold it only on order, instead of hawking it around from place to place, considerable economies could be made in distribution, which could be passed back to the producer. It is not possible at present to criticise these manufacturing charges to any practical effect, nor will it be possible to do so until records and accounts are kept in such a fashion as to render this feasible.

(c) *Conversion of Price of Commercial Butter into Price of Butterfat.*—This conversion is effected by multiplying the price of commercial butter by 1.18 on the assumption that 100lbs. of butterfat should make 118lbs. of commercial butter. The figure almost universally recognised in Victoria is, however, 120lbs. of commercial butter, and whatever may have been conditions in the past, a recent investigation undertaken at the request of your Commissioners, showed that under improved manufacturing conditions 120lbs. held good for South Australia as well. The facts are as follows:—

1. The returns from 23 factories in the 12 months ending on December 31st, 1932, were carefully examined with the following results:—

2. The total quantity of butterfat paid for by these factories was 13,591,089lbs. (121,349cwt.), and the total amount of butter made, 16,348,518lbs. (145,969cwt.). These figures give a mean over-run of 20.28, that is to say, 100lbs. of butterfat has given 120½lbs. of butter.

3. Since in the above connection the price of butterfat was based on the assumption that 100lbs. of butterfat would make 118lbs. of commercial butter only, whereas in actual practice it made 120½lbs., it can reasonably be stated that cream suppliers were short-paid to that extent, excluding extra services, over-rating, &c.

4. During this 12-month period—1932—the mean price paid for butterfat was 10.9d. per lb. Had the price been calculated upon the basis of 100lbs. of butterfat for 120lbs. of commercial butter instead of 118lbs. only, the mean price paid would have been 11.08d. per lb., that is to say, a difference of 0.18d. per lb.

5. On the 13,591,089lbs. of butterfat purchased by these 23 factories in 1932, short payment of 0.18d. per lb. would have been equivalent to an aggregate sum of £10,465, or a mean of £455 per factory per annum. On the other hand, on the basis of a mean individual supply of 10galls. of 45 per cent. cream per week, this sum distributed among 5,800 cream suppliers would represent less than £2 per supplier per annum.

Notwithstanding the relative unimportance of the sums involved, your Commissioners are of the opinion that so long as there is an understanding among buyers that no more shall be paid for butterfat than a fixed price based upon a rigid formula, it is essential that such formula should, as much as possible, correspond to reality, or in other words, that it should give the supplier full advantage of all the commercial butter that could be made from his butterfat by an efficient factory. It is generally recognised in Victoria that 120lbs. of butter from 100lbs. of butterfat was the normal anticipation of any efficient factory, and this anticipation has now been shown to have applied to South Australian factories in 1932, hence, your Commissioners recommend that until such time as there is a definitely free market for butterfat in South Australia, calculations used for fixing commercially the price of butterfat shall be legally based upon the principle that the cream supplier shall be entitled to a price which takes into account all the commercial butter that can be manufactured from his butterfat by a competently equipped and managed butter factory; and that provisionally the legal ratio shall be not less than 120lbs. of commercial butter from 100lbs. of butterfat sold.

It is obvious that to some extent the amount of butter made will depend upon the effectiveness of the factory methods in use, to some extent, too, the relationship of total butter made to total butterfat purchased will be a check on the general accuracy of the cream tests. But because some factories may be more or less inefficient is no sound reason why cream suppliers should be penalised for the inefficiency of manufacturers, in other words, if we are to have a fixed flat price for butterfat this price must be based upon the capacity of the efficient and not of the inefficient.

The relative positions of the 23 factories examined in 1932 are shown below:—

Number of Factories.	Lbs. of Commercial Butter made from 100lbs. of Butterfat.	
	Range. lbs.	Mean. lbs.
2	122.2 to 122.3	122.25
7	121.1 to 121.9	121.54
5	120.0 to 120.8	120.56
3	119.1 to 119.9	119.42
4	118.5 to 118.8	118.67
1	117.8	117.80
1	116.2	116.20
23	116.2 to 122.3	120.25

It will be observed that of these 23 factories nine did not come up to the standard of 120lbs. of butter to 100lbs. of butterfat; on the other hand, 13 of them showed more than 120lbs., all that can be said in the matter is that the less efficient must improve their methods.

6. *Payment of Cream on the Basis of Butterfat or that of Commercial Butter.*—

It is frequently argued that if cream were purchased by manufacturers on the basis of commercial butter, as is the case in New South Wales and Queensland, instead of on the basis of butterfat, as is the case over the rest of the world, the South

Australian cream supplier would stand to gain thereby. It is nevertheless exceedingly difficult to believe that such would necessarily be the case since given adequate supervision in either case, theoretically the results should be identical, and on a free market for butterfat they would be so in actual practice. It is somewhat significant that the Chief Dairy Instructor, Mr. H. B. Barlow—whose report on the subject is attached herewith as Appendix VII.—himself an advocate of commercial butter, should summarise the position as follows:—"When all is said the chief advantage of the Commercial Butter system is the ease with which it can be checked."

Payment on a butterfat basis is certainly the more logical of the two, the manufacturer buys butterfat, and not commercial butter. If he were compelled by law to pay for butterfat on the basis of commercial butter, then to all intents and purposes he would be acting as the manufacturing and selling agent of the cream suppliers, and corresponding charges would be deducted from all payments made. In the absence of the check of a free market, would it be easier to check the fairness of charges made under the Commercial Butter Plan than to correlate butterfat purchased with butter sold under the Butterfat Plan? Of the two, the latter task would probably be the easier. Moreover, intricate questions as to the legal ownership of the butter might arise until sales had been definitely effected.

In the circumstances, your Commissioners do not recommend any alteration to the current South Australian practice, namely, payment of cream on a butterfat basis.

7. *Relative Inferiority of South Australian Butter.*—It is generally admitted that the average South Australian butter is usually of lower quality than that made in New South Wales or Victoria, and that this relative inferiority is commonly reflected in reduced overseas prices. This statement must not, however, be taken for a sweeping condemnation of all butter manufactured in South Australia, some of which is indeed of excellent quality, particularly over the cooler portions of the year. But the statement is intended to give expression to the average commercial quality, which necessarily reacts upon the average overseas parity of South Australian butterfat, when divested of current export bounties.

Although, no doubt, it can be said that there are several minor factors that contribute to this relative lack of quality in our butter, the chief factor of all is unquestionably the absence in South Australia of large compact areas of typical dairying country, and all the natural consequences that derive therefrom. Incidentally, it can be stated here that the complete reclamation of the South-East and the gradual building up of its pastures must eventually make good this present national disability. At the present moment at all events, our cream comes for the most part from isolated mixed farms rather than from dairy farms, and frequently from wheat farms, upon which milk and cream are but unimportant sidelines. Hence deficiency in quality in butter is primarily traceable to the unsatisfactory conditions under which the raw material or cream is produced and handled.

Apart from probable incompetency among many producers, the main difficulty is insufficiency of daily herd production of cream coupled with the damaging influence of the relatively high temperatures to which the cream is usually exposed, and the long distances which the latter must usually cover before reaching the factory door. If on the average it should take a week to fill a can of cream, the latter would not as a rule leave the farm more than once a week, and unfortunately in the interim it would be exposed in summer to excessive air temperatures, and later on in conveyances, or at railway stations to still more damaging sun temperatures. Hence, it follows that in the summer months of the year there is very little cream that reaches South Australian factories that is not more or less inferior in quality, and unfortunately for the most part manufacturers in the interests of their turnover, have not hesitated in the past to grade cream of this character as

choicest, and even when forced by Departmental regulations to grade the cream at its true grade, to make no distinction between the price paid for choicest and that paid for inferior grades of cream. Obviously, tactics of this kind do not make for improvement in the quality of South Australian cream, and consequently in the quality of South Australian butter, and consequently again in the price paid for South Australian butterfat.

Quite recently a deputation of manufacturers waited upon the Director of Agriculture and asked that regulations under the Dairy Industry Act should be so framed as to compel cream payments in strict accord with the testers' sheets, and presumably of the graders' sheets, too. If this were done it would imply enforcement of differential payments for creams of varying grades, and if such enforcement were found to be incompatible with the provisions of the present Act, your Commissioners recommend its amendment towards such end.

It is their firm belief that accurate grading of cream, and differential payments for the same, are of material interest to the dairying industry as a whole, but particularly so to cream suppliers. The first result would be improvement in the average quality of cream in response to the stimulus of differential payments, this would lead to improvement in the average quality of our butter, to be followed eventually by overseas recognition and improvement in overseas parity, which would then render possible improvement in average butterfat prices. All such processes, however, are necessarily slow, and will involve initial disappointment unless taken in hand by firm but sympathetic educational guidance. The Department of Agriculture has at the present time a limited staff of dairy instructors, five in all, scattered over an immense area of country, it would not be practicable, nor is it suggested, that every cream supplier should be under the direct supervision of a dairy officer. But it is believed to be practicable, and indeed essential to real progress in the dairying industry of the State, that the country dairy officers should be in intimate contact with all factories and cream depots in their districts, and if the number of these officers is insufficient for the purpose then it should be increased accordingly. These officers should take every opportunity to inspect the cream as it is received at the factory door, and check the grading, it should be rendered obligatory upon all managers of factories and cream depots to supply district dairy instructors with a weekly list of the names and addresses of all cream suppliers whose cream had been graded during the course of the week below first grade, with such comments as the managers might think fit. A copy of each such statement should be forwarded to the Chief Dairy Instructor for noting and filing. It should then be the normal duty of the dairy officers to pay early visits of inspection to all those who had been supplying inferior cream, to inquire into the causes of the trouble, and suggest suitable means for the overcoming of them. In all such matters the Chief Dairy Instructor should be kept advised of the general position and of any results that might follow.

But should the cream supplier prove recalcitrant and refuse to act upon the dairy officer's advice, the latter is in the unenviable position of having no alternative but to recommend cancellation of the farmer's licence, a request which the Minister might refuse. This position has arisen very largely because of the refusal of Parliament to sanction regulations dealing with the handling of dairy products on the farm. It is the firm belief of your Commissioners that it is in the best interests of neither the dairy industry nor the community that the premises on which milk and milk products are handled should escape periodic inspection, and compliance with modern requirements of hygiene and sanitation. In the circumstances they respectfully recommend that adequate regulations under the Dairy Industry Act be re-submitted to Parliament, in the belief that a very strong case can be made for their acceptance.

C. SUMMARISED CONCLUSIONS AND RECOMMENDATIONS AS TO BUTTER.

After a careful consideration of the whole position, your Commissioners are satisfied that the main cause of the low butterfat prices of recent years is the progressive decline in London butter prices since January, 1929. They recognise, too, that these prices have been maintained appreciably above export parity by the functioning of the Paterson Scheme, a private Commonwealth concern which appears to have been admirably managed. It is based upon the principle of export bounties, paid from aggregate levies upon all butter manufactured in the Commonwealth, apart from Western Australia. With the increase in Commonwealth exports the aggregate levies have gradually been declining in value relative to the bounties they are meant to finance, and the scheme is now said to be in danger of extinction. Hence your Commissioners recommend—

Recommendation 21.—That in the event of the sudden closure of the Paterson Scheme, without adequate substitute, that the South Australian Government should offer no opposition to the expansion of the "Supplementary" South Australian Scheme.

The amount of farm butter made in South Australia varies from 20 per cent. to 30 per cent. of total production, all of which has escaped levies under the Paterson and Supplementary Schemes; and whilst the amount produced has been too small to affect the Commonwealth Scheme, it would certainly work to the disadvantage of a purely local scheme. And as the bulk of this butter is of very low grade and handled under defective conditions, it is recommended—

Recommendation 22.—That all farms manufacturing butter for sale or for barter shall be licensed and subject to regulations providing that the butter shall conform to the standards of the Food and Drugs Act, and that methods of manufacture and premises shall be reasonably hygienic and sanitary.

For some years back the Commonwealth export regulations have prohibited the use of any preservatives excepting common salt in the manufacture of butter, and, although at first there was some difficulty in getting butter so treated to keep well, improved modern methods of manufacture have proved that butter made without preservatives can be landed in Great Britain, and be distributed to British consumers in practically as good condition as it left Australia. It is, therefore, an anomaly that the dangerous practice of using preservatives in butter should still be allowed for butter intended for use on the local market. Hence it is recommended—

Recommendation 23.—That section 32 (3) of regulations of the Food and Drugs Act, 1908, issued on May 5th, 1932, relative to the use of preservatives in butter be repealed and a new section be drafted prohibiting the use of any preservative in the manufacture of butter with the exception of common salt.

After careful consideration of the whole position your Commissioners are satisfied that the suspicions of the cream suppliers that they are being defrauded by manufacturers are supported neither by facts nor by the probabilities of the case. Nevertheless, these suspicions are comprehensible enough. Suppliers, who lead comparatively isolated lives, find themselves compelled to accept prices which do not meet costs of production; they know that there is no price-competition among manufacturers, and that the fixed price is determined on a complicated formula by interested parties; and from the possibility of unfair action in this direction that they perceive they jump to the certainty, and thereafter see confirmation of their suspicions in every action of the manufacturers such as high cream grading to new customers, over testing, discrimination in the cost of collection of cream, &c.

Actually the position can be viewed as follows:—The commercial success of manufacturers, apart from efficiency, is mainly dependent upon adequacy of turnover, and their main aim may be said to be to attract cream suppliers, and to

retain them on their pay rolls; and whilst errors in testing or accounting will arise from time to time, as in the best regulated concerns, it is, nevertheless, inconceivable that large trading concerns, dependent for their success upon suppliers, should be foolish enough to risk the goodwill of the latter by the petty defalcations of which they are suspected.

The suppression of price competition, however, is the weak link in the manufacturers' case, for it is obvious that the price must be fixed upon a basis acceptable to all, efficient and inefficient alike, and it follows that the cream supplier does not under a fixed price get the true commercial value of his butterfat. As matters stand he can be said to receive the value that the less efficient manufacturers can afford to pay, and no more, whereas under freer conditions he would receive the value that the most efficient ones could afford to pay. The whole question hinges around what value should be placed upon what has come to be known as manufacturing costs, &c. The value at present claimed under the fixed price understanding is 2½d. per lb. of butter manufactured. Evidence submitted indicated that this figure would be subject to appreciable reduction, possibly ¾d. or thereabouts, under the healthy stimulus of free price competition.

Hence your Commissioners feel that if it were possible to establish in South Australia a free market for butterfat, and to render illegal any understanding among buyers as to a fixed price, butterfat would soon find its true commercial value, which would continue no doubt to vary with world parity prices, but would not be less than what the best equipped and managed factories could afford to pay. Evidently, too, in such circumstances the inefficient ones would have to mend their ways, or else disappear. It is, however, recognised that even if prohibition of price fixation were legally feasible, it would be difficult, if not impossible, to prevent a secret understanding on the subject among buyers on the basis of an accepted formula. Hence it is recommended—

Recommendation 24.—That the Crown Law Officers inquire into the legal feasibility of prohibiting price fixation of butterfat in South Australia, and express an opinion as to the possibility of enforcing such a prohibition against the combined opposition of buyers.

But as for the time being the establishment of a free market for butterfat in South Australia is highly problematic, it is advisable in the meanwhile that certain precautions be taken in order to allay the suspicions of suppliers, and if necessary, to protect them against possible exploitation. Towards this end your Commissioners recommend—

Recommendation 25.—That the manner in which records and accounts shall be kept by manufacturers, and balance-sheets presented by them, shall be prescribed in order to render possible accurate segregation of all major operations.

Recommendation 26.—That in the absence of a free market for butterfat, the terms of the formula by means of which the price of butterfat is to be determined shall be definitely fixed from time to time by Government representatives in consultation with representatives of the manufacturers. Such terms shall include costs of placing exported butter aboard ship, and all *intra-mural* factory costs, with due allowance for market risks and profits, but shall not include costs of conveying cream to the factory door or to railway siding, which costs should be borne by the cream suppliers.

As soon as data become available under Recommendation 25, the above costs shall be based upon the data of obviously well equipped and managed factories only.

Recommendation 27.—That in all calculations for the determination of the commercial value of butterfat it shall be legally recognised that the cream supplier is entitled to a price which takes into due account the total amount of commercial

butter which could be made from his butterfat by an efficient butter factory; and that provisionally the legal ratio shall be not less than 120lbs. of commercial butter from 100lbs. of butterfat sold.

Recommendation 28.—That for the double purpose of raising the average standard of South Australian cream, on the one hand, and of satisfying cream suppliers that their interests are under effective official supervision, on the other, the dairy branch of the Department of Agriculture should be strengthened in order to render possible more frequent and thorough factory inspections. Towards this end it is recommended that—

- (a) The holding back for 24 hours of carefully numbered samples of all cream tested in any one day, as requested by manufacturers, be strictly enforced, and that inspecting officers be instructed always to test random samples of the preceding day and to report deficiencies and errors to the Chief Dairy Instructor.
- (b) The true grading of cream be insisted upon and provision be made for differential payments of cream if necessary, by means of amendment of the Dairy Industry Act.
- (c) Payments by factories for cream to be strictly based upon the original sheets of graders' and testers' results, and penalties be provided for any contravention.
- (d) It be obligatory upon all factory managers to supply weekly returns to the Chief Dairy Instructor setting out names and addresses of cream suppliers whose cream had been graded below first grade during that week. On receipt of the same this officer shall take early steps to investigate the trouble and provide for necessary remedial measures.
- (e) Special regulations for the control of farm premises, and of milk and milk products handled thereon, should be resubmitted to Parliament, accompanied by a clear statement as to the urgent need of these regulations.

The objective of lower costs of manufacturing can best be achieved by the elimination of unnecessary transport costs and the reduction of the aggregate capital and labor costs of the factories to the lowest amount which is necessary.

There are now more factories in South Australia than are necessary to manufacture the cream available, and an increase in the capital investment in factories tends to increase rather than reduce manufacturing costs.

There is a tendency to encourage new factories in South Australia, due to the voluntary basis of the Paterson Scheme, since a new factory can commence operations under the shelter of the scheme and make no contributions to it.

While the Paterson Scheme is in operation it should be a condition of each butter factory licence that it should conform to the requirements of the Paterson Scheme Levy.

In the interests of economical production the Hon. the Minister should have power to refuse a licence to open a factory on the grounds that public convenience and necessity does not require it. Hence your Commissioners recommend—

Recommendation 29.—That power be sought under the Dairy Industry Act enabling the Minister of Agriculture to decline to issue a licence for a new butter factory on the grounds that neither public convenience nor necessity require it.

Finally, your Commissioners deem it their bounden duty and their pleasure to acknowledge the valuable assistance they received during the course of their inquiries from private individuals and officials, and from corporate bodies and

associations, both in South Australia and in the other States; they recognise that without such assistance this report, whatever its value, could not have been completed.

They wish also to express appreciation of the conscientious manner in which Mr. R. G. Hitchcox has attended to his secretarial duties.

We have the honor to be,

Sir,

Your Excellency's obedient servants,

W. J. DAWKINS, Chairman.

A. J. PERKINS, Member.

J. W. WAINWRIGHT, Member.

(Subject to dissent.)

R. G. HITCHCOX, Secretary.

Adelaide, October 20th, 1933.

DISSENT.

I regret very much that I am unable to agree with the recommendations herein dealing with the metropolitan milk supply concerning:—

- (1) Price control of milk for human consumption.
- (2) Restriction of each milk supplier by licence to a specified weekly quantity in country districts, and restriction of cows in the metropolitan area to a stated number.

1. Power to fix a price of milk for human consumption should be given (which should be used only if the necessity arises) in order to induce producers to go to the extra expense and trouble which is required to obtain a pure milk supply for human consumption under conditions laid down by the controlling authorities. All cities pay more for their milk supply than the commercial price of milk for butter, cheese, &c., because producers will not incur the necessary expense and trouble unless the extra price is offered; hence some form of price fixation or agreement has become usual; but the extra price offered should not be *more* than is necessary to recompense the producer for the extra expense and labor required in producing milk for human consumption.

If a higher price be fixed than is an adequate return for the service, many more people will demand the privilege of supplying, and a much greater quantity than is required will be striving to exploit the favored market.

2. *Restriction of Supply.*—The experience of price fixing in all countries has shown that if the price of any commodity in a market (State, National, or International) is fixed at a level that is out of balance with other related commodities in the market, it stimulates a greater supply of the higher priced article, and if some form of restricting the supply is not successfully established the market becomes glutted with the over-valued commodity. The objections to such restrictions are:—

- (1) The higher price which renders restriction necessary is a form of taxation of consumers for the benefit of producers. This may at times be justified, but Parliament is the properly constituted body to impose taxation.
- (2) The number of producers who are permitted to obtain the higher price is to be limited, and others who may desire to come in are to be excluded upon an arbitrary basis.
- (3) Producers outside the favored field who desired to come in would never be contented, and would regard their arbitrary exclusion as unjust.
- (4) The limitation of supply to a weekly quantity, and restrictions of herds, are artificial restrictions, which are arbitrary, and unjustifiably hamper healthy freedom of trade and individual liberty.

Annual Contracts.—The milk supply of a city is approximately constant throughout the year, and as increased capital must be invested by producers in providing a pure milk supply (as compared with cream supply), each milk producer should be able to sell a regular quantity throughout the year, and as it can be more economically produced under such conditions, milk wholesale firms in most cities make annual contracts with milk suppliers.

This practice of annual contracts has been adopted by wholesalers in all Australian cities, and also in Europe and America. In Adelaide this method of purchasing is hampered by the irregularity of the supply from within the metropolitan area. Metropolitan production increases during the July to December period, and falls off heavily during the January to June, or January to May period, when the city must rely upon country producers for most of its milk. This metropolitan surplus (when green fodder is plentiful) tends to rob the country producers of their trade during that period.

I suggest that metropolitan and country milk suppliers should be placed upon an equitable basis in marketing surplus milk, and that in order to secure this, metropolitan suppliers should be required, from time to time, to nominate a supply of milk which they are prepared to *regularly maintain* (within reasonable margins), and that all surplus to this (usually during July to December) must be used for cream and butter. A system of annual contracts between country milk suppliers and city wholesalers will then naturally develop under free conditions.

J. W. WAINWRIGHT.

October 13th, 1933.

APPENDIX VI.

Statement Supplied by the Secretary of the Stabilization Committee concerning the Relationship of Butterfat Prices to London Butter Prices.

Your letter of July 4th, setting out the text of various resolutions adopted at a conference of Branches of the Agricultural Bureau held at Mount Barker in May, has been considered by my Committee, and I have been desired to reply thereto as follows:—

Whilst recognising the close inter-dependence of the manufacturer and the producer in the butter industry my Committee cannot admit the right of the supplier to any form of control in the industrial and commercial matters of manufacture, marketing, and price fixing. The manufacturer of butter, like the manufacturer in any other industry, buys his raw material, and from the moment the property in the material passes to him he has to bear all risks. He immediately becomes liable to the supplier for payment for the butterfat, and, thenceforth, he has to carry multitudinous risks, such as deterioration, movement of the market, bad debts, &c. It is admitted that a peculiarity exists in this industry in that the seller places himself in the hands of the manufacturer for the correct measurement of the quantity and quality of the raw material delivered. The very circumstances of the trade make this inevitable, and realising this the Government has set up adequate machinery for seeing that this trust imposed by the supplier in the manufacturer is not abused. This machinery includes the filing of monthly returns by all manufacturers, full powers to audit records, to ascertain that such returns are true, and the widest possible powers of general inspection, in addition to which all suppliers have the right to call upon the Chief Dairy Instructor to make particular and detailed checks. With this unusual feature adequately covered so as to protect the supplier, the position of the butter manufacturer is, we repeat, in no way different from that of any other manufacturer. From this emerges the fact that the term "manufacturing charges" is a misnomer. A charge cannot exist without there being some second party to the charge, and as the raw

material, immediately it has been measured, becomes the property of the manufacturer, the element commonly called "manufacturing charges" is his calculation of the expenses of manufacture and marketing and provision for his profit. These expenses cannot possibly be constant, because the butter is sold not only in Australia, but to numerous buyers in Great Britain and the East, and it rarely happens that all butters command exactly the same price. The manufacturer aims to allow a margin that on the average will be adequate. No instance is known to members of my Committee of parties who carry no financial responsibility for the operations involved being given even partial control of an industry. It is true that Parliament regulates the charges of such monopolies as the gas and electric light industries in this State, but this power is exercised because of the privilege of monopoly which Parliament grants the companies rendering these services. When the producer asks for control of the commercial functions in the dairy industry he is not in a position to confer upon the manufacturer any compensating protection. The manufacturer is left open to the full blast of free competition and the risks of the general economic situation. It is he who in the long run has to meet his wages bill and his obligations to his creditors, and, consequently, he holds that demands for control of his ordinary commercial operations can find no support in either equity or precedent. Furthermore, the existence of a Government butter factory and the active presence of its representative upon the Price-fixing Committee are sufficient guarantee that manufacturers are not extracting unjustifiable profits from the industry. If this were so it would be reflected in the trading results of the Government-owned factory, but reference to the report of the Parliamentary Standing Committee on Public Works on the Port Adelaide Freezing Works and Butter Factory, and to subsequent reports of the Auditor-General, will show that its profits from the manufacture of butter, even when they occur, are negligible. This is an important fact, because the Government butter factory was intentionally established as a "check" factory. Also on the Price-fixing Committee are the representatives of two large co-operative organisations established and controlled by primary producers. In fact, we can think of no other industry in the State where the sellers of a raw material have such facilities for exercising influence upon the buyers of the product as they have in the butter trade. The foregoing remarks cover the questions raised by the resolutions 1 and 3.

All that need be said in respect of resolution 2 is that for several months factories have been so notifying suppliers, and have even gone to the extent of enlisting the assistance of the Government Dairy Inspector to see that the policy is carried out in a thorough manner.

Finally, we refer to your request for a statement showing how the price of butterfat in Adelaide is reconciled with the London price of butter, and here we are confronted with the principle dealt with above. We have not heard of wheat growers claiming a right to demand an explanation from merchants as to how the local price of wheat is reconciled with the price in Liverpool or Chicago, or similar demands from the breeders of cattle and the growers of apples. All merchants are compelled to take into consideration a multitude of factors, all of which may, and frequently do, vary from day to day, so that it requires a close knowledge of the particular brand of commerce concerned even to be able to follow the calculations involved. An explanation that holds good to-day may not apply correctly at another date, and in setting out the position at any given time there is a danger that when departures from it are observed they will be regarded suspiciously by outsiders not familiar with the factors operating. Consequently you will see that your last request confronts the members of my Committee with two difficulties:—(1) They do not grant that they, more than any other merchant or manufacturer, are required to make public their commercial calculations; and (2) they are alive to the danger of any such information, if

given, being gravely misinterpreted by those unfamiliar with the countless factors bearing upon their affairs. But although firmly maintaining this position, they desire to work amicably with all other sections of the industry, and in the hope that a concession to your request on this occasion will help towards this end they have authorised me to give merely as an instance the method followed in establishing the price on Monday afternoon, the 18th July, this information being set out in the attached statements.

I. PRICES—GENERAL STATEMENT.

My Committee incline to the view that many of the confused ideas regarding the price of butter arise from the fact that the prices shown in the cabled market reports from London are accepted by readers as if these were the actual prices realisable instantaneously by manufacturers for stocks in Adelaide. It should always be remembered that the cables give only the price of butter actually "on spot" in London, whereas butters leaving the South Australian factories at that date cannot arrive in London until six weeks later. Owing to this delay it is fallacious to attempt to find absolute agreement at any given date between London and Adelaide prices. If a long period is taken for comparison, a complete year for instance, a close agreement will be found to exist.

South Australian butter manufacturers, as well as those in other States, have found that because of this constant fluctuation in the London price, the figure offered by London merchants for butter f.o.b. Adelaide, or c.i.f. and e. constitutes in the long run the most reliable basis from which to work prices.

The attached statement A is a calculation of the price realised by the manufacturer on the basis of sales at 103s. (sterling) per cwt. in London for butter sent to that market on consignment.

Statement B is a similar calculation on the basis of c.i.f. and e. London sales at 101s. (sterling).

These prices have been adopted for illustration because, as indicated in the final paragraph of our letter, they form the basis adopted by the Committee in establishing the local price on the 18th instant. Normally the price is fixed every Monday afternoon on the quotation then ruling. The fluctuating nature of the London market already referred to makes variations during the week inevitable, but, as will be readily realised, the average is found to be fair. It is an impossible ideal to make the local market move in detailed sympathy with the London market. To illustrate this aspect of the question, although 101s. c.i.f. and e. was taken as a basis for the week commencing the 18th instant, in the latter part of the week 99s. was the maximum price obtainable. In this manufacturers suffered, but, of course, compensation comes when the movement is in the other direction. It is, to repeat, the average position that must always be used as a basis for comparison.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

II. STATEMENT A.

Net return of manufacturers of butter shipped on consignment and sold in London for 103s. per cwt., which was the spot price in London last week:—

	Shillings per Cwt.
Choicest butter sold in London	103.00
Less London charges, including port dues, lighterage, land, housing, delivering, rent, cabling, trade discount, commission and <i>del-credere</i> risk, which average 4½ per cent.	4.89
	<hr/> 98.11
Plus 25 per cent. exchange	24.52
	<hr/> 122.63
Deduct freight to London, 8s. per cwt., plus 18 per cent.	9.44
Insurance at 6s. 10d. per cent., plus 25 per cent.41
	<hr/> 9.85
	<hr/> 112.78
Add Paterson bounty	28.00
	<hr/> 140.78
Less Australian charges (cost of cases, freezing, wharfage, cartage to Outer Harbor and putting aboard, Commonwealth grading fee, and Dairy Council levy)	6.83
	<hr/> 133.95
Less levy to Paterson plan	16.33
	<hr/> 117.62

Net price to manufacturer in Adelaide on butter sent on consignment and sold in London at 103s. per cwt. would be 117s. 7d. per cwt. in Australian currency.

III. STATEMENT B.

Net value to manufacturer, in Australian currency, of butter sold at 101s. per cwt. c.i.f. and c., London:—

	Shillings per Cwt.
Value of choicest butter	101.00
Deduct London selling agent's commission of 1 per cent.	1.01
	<hr/> 99.99
Add exchange at 24.75 per cent., this being the rate obtained on demand draft	24.75
	<hr/> 124.74
Deduct freight to London at 8s. per cwt., plus 18 per cent.	9.44
Insurance at 6s. 10d. per cent., plus 25 per cent.41
	<hr/> 9.85
	<hr/> 114.89
Deduct Australian charges (cost of cases, freezing, wharfage, cartage to Outer Harbor and putting aboard, Commonwealth inspection fee, and Dairy Council levy)	6.83
	<hr/> 108.06
Add Paterson Scheme bounty	28.00
	<hr/> 136.06
Less levy to Paterson plan, 1½d. per lb.	16.33
	<hr/> 119.73

Which is equivalent to 1.83s., or 12.83d. per lb. net to the manufacturer. As the price being paid by most manufacturers for butterfat is 1s. per lb., it will be seen that from the over-run, the manufacturer received 2.66d. per lb. to cover the cost of manufacture, interest, depreciation and profit.

The foregoing shows the result, as already stated, where the manufacturer actually secured 101s. for his butter; not all manufacturers succeeded in doing this.

APPENDIX VII.—*Statement by Chief Dairy Instructor Concerning Relative Advantages and Disadvantages of Cream Payments on Basis of Commercial Butter or on Basis of Butterfat Respectively.*

With reference to my opinion as to which is the better method of payment, the commercial butter system of butterfat basis—briefly, the difference in the two systems is:—

Commercial Butter System.—The cream is tested for butterfat content, and an estimation made, by the use of an approved chart, of the corresponding amount of commercial butter which can be made from the ascertained amount of butterfat.

In testing (Babcock method) a modification is made to the usual practice, inasmuch as the amount of cream taken (to represent 9 grammes) is measured with a pipette, and with rich cream an allowance is made in the chart to compensate for variations in specific gravity.

On account sales, the net pounds of cream, test, and estimated pounds of butter are shown, and the gross price per pound of butter is stated. The necessary charges to be taken from this price are then deducted.

Butterfat Basis.—The cream is tested in the orthodox manner of weighing out 9 grammes of cream, and the amount of butterfat in the cream is arrived at.

No charges are shown on the account sales, but a net price for butterfat is arrived at by taking all charges into consideration.

In favor of the butterfat system of payment it may be stated that it is universal throughout the world, except in New South Wales and Queensland—and, at the same time, with the exception of Denmark—these two States are practically the only large dairying centres in the world which are practically wholly controlled by purely co-operative interests run by the producers themselves.

In my opinion, the chief reasons why the Commercial Butter System is better for the producer are:—

1. The price quoted on the account sales is comparative with the published wholesale price of butter.
2. As the contents of the cream bought, the butter manufactured, and the butter sold by the factory are all in the terms of commercial butter, a comparison is easily arrived at.
3. Granted efficient Government control, which stipulates that all over-run, over and above the chart estimation, must be returned to the suppliers *pro rata*, the supervision of factory payments is a simple matter, and suppliers can be assured that the factory does not sell any butter which they, the suppliers, are not credited with.

Thus, provided the factories pay the full market price, their only means of making profits will come from the manufacturing charges.

The chief objections I see to the Butterfat System of payment are:—

1. It is very difficult for the average farmer to appreciate the difference between butterfat and butter. This often leads to a considerable amount of misunderstanding.

2. Theoretically, it is possible to make 122lbs. of butter from 100lbs. of butter-fat, but in practice only about 120lbs. are made commercially; nevertheless, because it is possible to make 122lbs. of butter, when checking the books, 122lbs. must be allowable. In my opinion, this gives the factories at least 2 per cent. to "play with."
3. In addition, it is by no means a simple matter to check butterfat paid for with butter manufactured and sold.
4. The fact that no charges appear on the account sales under the Butterfat System also tends to make the supplier suspicious.

When all is said, the chief advantage of the Commercial Butter System of payment is the ease with which it can be checked.

H. B. BARLOW, Chief Dairy Instructor.

September 21st, 1933.

PRACTICAL POULTRY MANAGEMENT.

The Library of the Department of Agriculture acknowledges the receipt of "Practical Poultry Management" under the joint authorship of J. E. Rice, B.Sc. (Agric.), and H. E. Botsford, B.Sc. (Agric.) The volume is profusely illustrated and deals with every phase of the breeding, rearing, and marketing of poultry and is one which should prove equally informative to students and commercial poultry keepers. Published by Messrs. Chapman & Hall, 11, Henrietta Street, Covent Garden, London, W.C. 2. Price, 16s. 6d. net.

COMPOST HEAPS FOR THE GARDEN.

The following information relative to the preparation of a compost heap has been supplied by Mr. W. J. Spafford, Deputy Director of Agriculture, in response to an inquiry received from a subscriber to the *Journal of Agriculture*.

1. *Is it essential to add Farmyard Manure?*—As a rule the addition of farmyard manure does not improve the compost, because most of the material put in the heap consists of plants which contain all of their original nutriment, whereas farmyard manure consists of a mixture of the remains of plants after animals have extracted some of the nutriment and poor quality organic matter used as litter, such as straw, &c. The presence of some farmyard manure may tend to hasten decomposition, but this is generally rapid enough, provided that the heap is kept moist.

2. *Will the addition of Artificial Manure help?*—Most compost heaps do not contain sufficient phosphorus and some nitrogen is lost in decomposition and so the addition of a phosphatic manure and some sulphate of ammonia will add considerably to the manurial value of the compost and lead to a fuller and more rapid decomposition. Poor organic matter, like straw, sticky dry weeds, over-mature plants, &c., can be converted into good manure by the addition of the artificials already referred to and some lime added as well. When straw is used about $\frac{1}{2}$ wt. of sulphate of ammonia, 1wt. finely ground limestone, and a little finely ground raw rock phosphate is added per ton of straw stacked, and the heap is kept damp and well aerated.

3. *Should Lime be added?*—Slaked lime or finely ground limestone can be added to a compost heap with advantage to the finished product. It encourages a complete decomposition, and its presence improves soil texture when the heap is used as a manure. About 1wt. per ton of compost is a liberal application, and it can be put into the heap by sprinkling it on layer after layer as the building of the heap proceeds. Freshly burnt lime should not be used as it delays fermentation and leads to the loss of nitrogen as ammonia.

SHEEP FEEDING EXPERIMENT CONDUCTED AT ROSEWORTHY AGRICULTURAL COLLEGE.

MAINTENANCE RATION UNDER SOUTH AUSTRALIAN CONDITIONS.

[By S. E. WHICKER, D.D.A., Stockman.]

INTRODUCTION.

The hand-feeding of sheep within the agricultural areas of South Australia is of great importance to the farmer and the State; a shortage of feed during two or three months of the year considerably reduces the number of stock that can be carried, unless the sheep are hand-fed over this short period. In drought years the economic hand-feeding of sheep is of even greater importance.

Increasing attention is being shown to fat-lamb raising as a means of stocking farms. Under these conditions, pregnant ewes comprise the greater portion of the stock to be fed. During a drought year wethers are disposed of to save the feed and the pregnant ewes retained because these are necessary to replenish the flock, and will repay the cost of feeding. It is a natural assumption, therefore, that any information on the hand-feeding of pregnant ewes will be of value and interest to sheepmen. It may be argued that suitable feed for dry sheep would be suitable feed for pregnant ewes, but experience has shown that where pregnant ewes are being hand-fed complications very often arise. In the last stages of gestation a heavy strain is placed on the body of the ewe to supply the requirements of the developing foetus, or foetuses. At this period numerous deaths very often occur amongst pregnant ewes which are being hand-fed. These deaths under South Australian conditions are largely due to what is known as "Twin Lamb Disease" (T.L.D.), sometimes referred to as "Toxaemia of Pregnancy Disease" (T.P.D.). At present very little is known of the history or cause of this trouble, and any feed which will maintain pregnant ewes without an outbreak would be invaluable, primarily as a means of safe feeding during periods of feed shortage and, at the same time, have a secondary significance of great importance in that the knowledge so gained would narrow down the dietetical problem connected with T.L.D., and perhaps lead to the partial elucidation of the cause. With the idea of gathering data along these lines the investigations reported herein were initiated at Roseworthy College. Although so far the tests have only been carried out over one season, it is considered that the results are of sufficient interest to justify publication.

REVIEW OF LITERATURE.

In reviewing literature on the subject of hand-feeding sheep under Australian conditions it appears that while most of the work has been carried out with dry sheep (references 1, 2, 3, and 5), in those cases where the experiments have been conducted with pregnant ewes (references 4 and 6) no trouble has been experienced with Twin Lamb Disease. One of the chief difficulties under College conditions, and this is true of many other parts of South Australia when hand-feeding pregnant ewes during the periods of temporary feed shortage, is the almost regular occurrence of Twin Lamb Disease. This is particularly so where crossbred or Merino ewes in lambs to rams of British breeds are concerned.

Most of the work carried out in other States emphasises oats as a valuable and reliable supplementary concentrate. Further, cereal ensilage supplemented with oats as a ration has been likewise used with successful results.

SCOPE OF EXPERIMENT.

Fodders Used.—On most farms there are three sources of sheep-feed reserves which can be conveniently and cheaply stored—these are ensilage, hay, and oats—they are accessible to all farmers within the agricultural areas. These feeds were therefore taken as the bases of the main rations. Because it was considered that ensilage alone might not be very suitable, a fourth ration was made by using bran with ensilage. Linseed nuts were included as a fifth ration, firstly because they are readily procurable as a concentrated supplement to roughage of low feeding value, and secondly in order that a comparison between these and feeds produced on the farm could be obtained. Finally, because Twin Lamb Disease was likely to be a limiting factor in the suitability of feeds green lucerne was included with the hope that it would provide a control lot. Serious outbreaks of T.P.D. do not usually occur when early greenfeed is available in the paddocks during the three weeks preceding lambing.

Sheep.—To provide sufficient sheep for six lots of 20 sheep each, 60 Merino and 60 Dorset Horn-Merino half-bred ewes, all full mouthed, were mated to Southdown rams on November 22nd. The rams were removed on January 11th.

SCHEME OF EXPERIMENT.

In order that this test could be considered in the light of supplementary feeding under paddock conditions, each lot was confined to a fenced plot of approximately two acres carrying long wheat stubble. Each plot had been grazed after harvest till it was considered that hand-feeding in addition to the stubble grazing would be necessary. In an attempt to equalise possible variations in the value of the feed on each plot, each lot was moved to the next succeeding plot each week after weighing. The 60 Merino ewes were divided off into even lots of 10, as also were the 60 Dorset Horn-Merino half-bred ewes. Each lot was then made to contain 10 Merino and 10 Dorset Horn-Merino ewes. Each ewe was ear tagged to allow the recording of individual weights, and the sheep in each group were branded with a numeral on the fleece to avoid any possibility of confusion. A platform scale with a frame and doors was used for weekly individual weighings.

In order to form a basis on which to compare the various supplements, the rations to be fed were calculated on a protein basis, seeing that protein would be the most essential constituent to add to the stubble grazing, mostly of a carbohydrate nature.

The maintenance requirement of 0.50lbs. of protein equivalent per head per week (reference, Wood 7) was used as a basis for each ration. The rations were calculated accordingly.

A lick consisting of coarse salt, 100 parts; superphosphate (45 per cent.), 60 parts; and Epsom salts, 10 parts, was supplied to each lot.

A week was allowed for the sheep to become accustomed to the experimental feeds and the conditions before the initial weights were recorded.

•
RATIONS.

At first the rations used were calculated from assumed analyses of the feeds. While the test was in progress representative samples of the feeds in use were analysed in the College chemistry laboratory, and slight adjustments in the rations were necessary to correct the protein equivalent supplied to each lot. The alterations in the rations were made after the fourth week, on March 22nd.

In Table I. are shown the rations supplied:—

TABLE I.

Lot.	Number of Sheep.	Daily Ration per Sheep.	
		22nd Feb. to 21st March.	22nd March to 19th April.
1	20	1lb. 6ozs. Chaff	1lb. 6ozs. Chaff
2	20	15ozs. Oats	1lb. 3ozs. Oats
3	20	4lbs. 2ozs. Ensilage	5lbs. 5ozs. Ensilage
4	20	3lbs. 6ozs. Ensilage	3lbs. 13ozs. Ensilage
		4ozs. Bran	4ozs. Bran
5	20	4-6ozs. Linseed Nuts	4-8ozs. Linseed Nuts
6	20	3lbs. Green lucerne	2lbs. 10ozs. Green Lucerne

The chaff, silage, oats, and lucerne were all produced on the College farm. The chaff was oaten, and on analysis was found to contain must less fibre than in a normal sample. The oats were a fair sample of feed oats from the 1932 harvest. The ensilage was chaffed ensilage from a concrete tub silo, and was made from stubble pasture containing wild oats, 24 per cent.; barley grass, 23 per cent.; burr trefoil, 23 per cent.; wheat, 19 per cent.; cultivated oats, 10 per cent., and odd weeds. It was a good sample of olive-green sour ensilage. The bran and linseed nuts were purchased.

ANALYSES OF FOODS.

In Table II. are shown the analyses of the foods:—

TABLE II.

Food.	Composition.					
	Dry Matter.	Protein.	Oil.	Carbo-hydrate.	Fibre.	Ash.
Chaff	83.2	7.5	1.4	52.0	17.8*	5.0
Oats	90.2	7.6	4.1	66.4	8.8	3.3
Ensilage	34.2	2.6	0.8	14.7	11.6	4.5
Bran	87.3	11.9	3.2	59.9	7.8	4.5
Linseed nuts	89.9	28.7	1.2	45.8	8.2	6.0
Green lucerne	25.8	4.9	0.7	11.5	6.2	2.5

*Each food with the exception of chaff shows a normal analysis. In this particular chaff, the fibre is very low.

In Table III. are given the digestible nutrients:—

TABLE III.

Food.	Digestible Nutrients.				
	Crude Protein.	True Protein.	Oil.	Carbo-hydrate.	Fibre.
Chaff.....	5.6	4.8	1.0	32.8	10.7
Oats	6.6	5.3	3.4	51.1	2.2
Ensilage	1.7	1.0	0.4	8.2	6.4
Bran	8.9	7.3	2.2	42.5	1.6
Linseed nuts	24.7	23.3	1.1	36.6	4.1
Green lucerne	3.5	1.9	0.4	7.6	2.7

The protein requirement per week on which the calculation of the rations is based is expressed in terms of protein equivalent, which equals digestible pure protein plus half the remaining digestible nitrogenous substances. Assuming the live weight of a sheep is 130lbs., the requirements per week for maintenance are, according to Wood (7):—Dry matter, 28.5; net starch equivalent, 10.5; protein equivalent, 0.50lbs.

The gross starch equivalent is calculated from digestible nutrients by the method given by Wood (7) thus:—Pure protein multiplied by 1.25, plus other nitrogenous substances multiplied by 0.6, plus oil multiplied by 2.3, plus carbohydrate multiplied by 1, plus fibre multiplied by 1, which equals the fuel value of 100lbs. as starch.

The net starch equivalent or production value is calculated proportionally from this, the proportion being that obtained from Wood's (7) figures. The net starch equivalents give the best available figures for the production value of the foodstuffs, while the gross starch equivalents give the heating or fuel value. The net equivalent is equal to the gross equivalent less energy expended in digestion.

The nutritive ratio is calculated from digestible nutrients, and is obtained by dividing the crude protein into the sum of oil, multiplied by 2.3, plus carbohydrate, plus fibre.

In Table IV. are shown the starch equivalents and nutritive ratios of the foods:—

TABLE IV.

Food.	Daily Ration in ozs.	Starch Equivalent of 100lbs. of Foodstuffs.		Nutritive Ratio.
		Gross.	Net.	
Chaff	22	52.3	39.8	8.2
Oats	19	68.5	63.0	9.3
Ensilage	85	17.2	11.6	9.1
Ensilage	61	17.2	11.6	9.1
Bran	4	59.3	35.0	5.5
Linseed nuts	4.8	73.1	64.5	1.7
Green lucerne	42	14.6	10.1	3.2

RESULTS.

In this experiment the results are to be gauged as much from the health of the sheep with respect to the appearance of T.L.D. as from the gain or loss of weight.

Health.—Cases of T.L.D. occurred in all lots with the exception of the lot fed on ensilage alone. On the occurrence of the second definite case in each lot that particular lot was removed from the test, because treatment of these cases once they are definitely established has, so far, met with little success, and nothing could be gained by a needless slaughter of ewes and lambs once the fact that the disease had been produced in a particular lot had been established.

On April 19th, 1933, the last general weighing was conducted. Three groups were carried on from this date with the object of allowing cases of T.L.D. to

make their appearance; these were weighed as usual, but the weights have been deleted from the results because the numbers in each group had been reduced on account of some ewes having lambed. Further, as some lots had been removed the data are not strictly comparable. Also at this time sufficient new grass had made its appearance in the plots to influence the weights.

As the first cases were not obtained until rain and cold winds were experienced, the record of rainfall and maximum temperatures at this period in relation to the incidence of disease have been examined. This is shown in the accompanying graph. In addition to this the loss in weight of the affected animals, together with the mean loss of 10 sheep of the same breeding in the lot, is recorded.

In Table V. are shown the total mean loss in weight of animals affected by T.L.D., as compared with the total mean loss in weight of the 10 sheep of the same breed and feeding:—

TABLE V.

Lot No.	Feed	Ear tag of Ewe.	Date.	Breed.	Total Mean Loss of Weight of Case.	Mean Loss in Weight of 10 Similar Ewes.
1	Chaff	76	17/4/33	Merino	12.8	7.7
		93	18/4/33	Merino..	13.3	7.7
2	Oats.....	8	13/4/33	Merino..	2.6	3.4
		781	23/4/33	Merino..	8.0	3.4
3	Ensilage	No cases				
4	Ensilage and bran .		13/4/33	Merino..	6.6	9.1
			14/4/33	Merino..	7.7	9.1
5	Linseed nuts	175	21/4/33	Dorset-	16.3	7.2
6	Green lucerne	2	5/5/33	Merino	5.1	7.4
		133	6/5/33	Dorset-	2.1	5.3
				Merino		

Table V. shows that four cases lost more while five cases lost less weight than the average loss in weight of the group of 10 sheep. Up to April 19th, 1933, only the chaff, oats, and ensilage plus bran fed lots had shown definite cases. On April 21st, 1933, the lot fed on linseed nuts showed a case, and as many of the ewes appeared cold, miserable, and weak this group was also removed. At May 2nd, 1933, neither the ensilage nor the green lucerne lot had produced a case, and as the paddock under use was required for tillage these two groups were removed to the sheep yards, there being 15 ewes left in the ensilage group and 10 in the lucerne group yet to lamb. On May 5th, 1933, just three days after removal to the yards, a case occurred in the lucerne lot. On the 6th another case occurred, and the remaining ewes were released. No cases occurred in the ensilage fed lot, and the ewes were released on June 8th, there being no pregnant ewes left. It should be noted that when these lots were removed to the yards

Weighing the Sheep.

they were limited to the ration supplied, and no roughage was available. The ensilage group was not consuming all the ration supplied. It is not possible to say whether the lowering of roughage had any effect upon the sudden appearance of cases in the lucerne lot.

As the lot fed on green lucerne showed cases of T.L.D., it is worth noting here that of the remaining 323 pregnant ewes on the College property only one case of T.L.D. occurred. This sheep was a Border Leicester-Merino half-bred ewe, and on *post mortem* was found to be carrying triplet lambs.

By careful grazing and interchange of the stubble paddocks, which in some cases contained a good growth of wire weed or hog weed (*Polygonum aviculare*), it was not necessary to resort to hand-feeding outside the experimental feeding flock.

Variations in Bodyweight.—In Table VI. the initial and final weighings of each individual sheep in the experiment are given together with the variations. In Table VII. are shown the mean initial weight and the mean variations from initial mean weight in pounds:—

TABLE VII.

Lot No.	Feed.	Mean Initial Weight.	Mean Variations from Initial Weight at each Weighing.						
			1/3/33.	8/3/33.	15/3/33.	22/3/33.	31/3/33.	5/4/33.	19/4/33.
1	Chaff	128.80	+ 3.85	+ 0.65	— 0.20	— 3.15	— 3.50	— 5.75	— 6.95
2	Oats.....	131.90	+ 3.30	+ 2.65	+ 1.00	— 0.25	— 1.25	+ 1.20	— 0.60
3	Ensilage ..	133.25	+ 0.10	— 1.90	— 2.50	— 5.85	— 4.00	— 4.65	— 6.35
4	Ensilage + bran	131.90	+ 0.50	— 0.40	— 2.85	— 2.60	— 4.10	— 1.65	— 6.50
5	Linseed nuts	125.00	+ 3.45	— 1.05	— 0.80	— 3.50	— 3.50	— 2.25	— 10.75
6	Green lucerne	134.50	+ 0.25	+ 2.35	+ 2.35	+ 0.65	— 0.55	+ 1.70	— 8.30

In Table VIII. are given the mean percentage variation from initial weights:—

TABLE VIII.

Lot No.	Feed.	Mean Percentage Variations from Initial Weight at each Weighing.						
		1/3/33.	8/3/33.	15/3/33.	22/2/22.	31/3/33.	5/4/33.	19/4/33
1	Chaff	+ 2.99	+ 0.51	— 0.16	— 2.45	— 2.72	— 4.46	— 5.40
2	Oats.....	+ 2.50	+ 2.01	+ 0.76	— 0.19	— 0.95	+ 0.91	— 0.46
3	Ensilage	+ 0.75	— 1.43	— 1.88	— 4.39	— 3.00	— 3.49	— 4.77
4	Ensilage + bran...	+ 0.38	— 0.30	— 2.16	— 1.97	— 3.11	— 1.25	— 4.93
5	Linseed nuts	+ 2.76	— 0.84	— 0.64	— 2.80	— 2.80	— 1.80	— 8.60
6	Green lucerne	+ 0.19	+ 1.75	+ 1.75	+ 0.48	— 0.41	+ 1.26	— 6.17

The figures shown in Table VIII. have been used to plot the accompanying graph.

In Table IX. are shown the losses from initial to final weights, both absolute and as a mean percentage of initial weight, also the probable error, range of variation, and standard deviation:—

TABLE IX.

Lot No.	No. of Sheep.	Absolute Losses of each lot from Initial to Final Weight.	Mean Loss in Weight and Probable Error as Percentage.	Range of Variation.	Standard Deviation.
1	20	139lbs.	5.40 % \pm .387	\pm 0 to - 15	3.37
2	20	12lbs.	0.45 % \pm .533	+ 8 to - 9	4.69
3	20	127lbs.	4.77 % \pm .427	+ 1 to - 14	3.80
4	20	130lbs.	4.93 % \pm .653	+ 5 to - 15	5.76
5	20	215lbs.	8.60 % \pm .480	- 2 to - 23	4.02
6	20	166lbs.	6.17 % \pm .427	- 2 to - 15	3.91

The standard deviation is a measure of variability upon which the calculation of the significance of results is based.

In Table X. is shown the significance of the difference between the mean loss in each group as compared with every other group:—

TABLE X.

Lot.	Feed.	Mean Loss as Percentage.	Lot.	Feed.	Mean Loss as Percentage.	Diff. in % Loss.	S.E. of Difference.	Significance.
1	Chaff	5.40	2	Oats.....	0.45	4.95	0.99	Highly
1	Chaff	5.40	3	Ensilage	4.77	0.63	0.86	Not
1	Chaff	5.40	4	Ensilage + bran	4.93	0.47	1.14	Not
1	Chaff	5.40	5	Linseed nuts	8.60	3.20	0.92	Highly
1	Chaff	5.40	6	Green lucerne	6.17	0.77	0.86	Not
2	Oats.....	0.45	3	Ensilage	4.77	4.32	1.02	Highly
2	Oats.....	0.45	4	Ensilage + bran	4.93	4.48	1.26	Highly
2	Oats.....	0.45	5	Linseed nuts	8.60	8.15	1.07	Highly
2	Oats.....	0.45	6	Green lucerne	6.17	5.72	1.02	Highly
3	Ensilage	4.77	4	Ensilage + bran	4.93	0.16	1.17	Not
3	Ensilage	4.77	5	Linseed nuts	8.60	3.83	0.96	Highly
3	Ensilage	4.77	6	Green lucerne	6.16	1.40	0.92	Not
4	Ensilage + bran	4.93	5	Linseed nuts	8.60	3.67	1.22	Highly
4	Ensilage + bran	4.93	6	Green lucerne	6.17	1.24	1.14	Not
5	Linseed nuts	8.60	6	Green lucerne	6.17	2.43	0.96	Significant.

A study of the above table reveals that from the point of view of loss of body weight the oat ration has given a significantly better result than all other rations; that there is no significant difference between chaff, ensilage, ensilage-

plus bran and green lucerne when each ration is compared with the other three; that the linseed nuts ration shows a greater loss from initial to final weight than any other food. The loss in weight on linseed nuts and green lucerne was very heavy when cold weather was experienced; this may be attributed to the fact that both are very deficient in carbohydrate, and as carbohydrate would be very necessary during cold weather to maintain body heat these foods might be expected to fall short in maintenance requirements. During cold weather it would probably be beyond the powers of the ewes to obtain sufficient carbohydrate over and above that required for digestion from straw. By feeding 4.8ozs. of linseed nuts, with a nutritive ration of 1 : 1.7, very little carbohydrate would be provided.

Response of Merino and Half-bred Dorset Horn-Merino to Hand-feeding.—In Table XI. is shown the difference between the mean loss of the Merino ewes in all groups, as compared with the mean loss of the Dorset Horn-Merino ewes in all groups:—

TABLE XI.

No. of Ewes of Each Breed.	Merino.		Dorset Horn-Merino.	
	Mean Loss.		Mean Loss.	
	Lbs.	Percentage of Initial Weight.	Lbs.	Percentage of Initial Weight.
60	7.96	7.22	6.05	4.04

It would appear from these figures that the half-bred Dorset Horn-Merino ewes responded better under the feeding conditions than did the Merino ewes.

Food Consumption.—In Table XII. are given the total amounts of food supplied, together with the amounts remaining and consumed:—

TABLE XII.

Lot No.	Feed.	Supplied.	Remaining.	Consumed.
		Lbs.	Lbs.	Lbs.
1	Chaff	1,540	248	1,292
2	Oats	1,190	—	1,190
3	Ensilage	5,285	101	5,184
4	{ Ensilage	4,025	—	4,025
	{ Bran	280	—	280
5	Linseed nuts	329	—	329
6	Green lucerne	3,150	—	3,150

It will be seen from the above that the chaff lot and the ensilage lot did not consume all the feed supplied. In the chaff lot amounts varying from 10lbs. to 73lbs. weekly remained. Amounts varying from 3½lbs. to 46½lbs. weekly remained from the lot fed on ensilage. In the chaff lot the 73lbs. were left the first week, while in the ensilage lot the 46½lbs. were left during the last week.

Salt Lick Consumption.—Although of only minor importance the salt lick consumption is given here for the whole period of the test.

In Table XIII. is shown in pounds the total consumption for each group:—

TABLE XIII.

Lot.	Feed.	Total Salt Lick Consumed in Lbs.
1	Chaff	28·7
2	Oats	20·5
3	Ensilage	28·3
4	Ensilage + bran	26·1
5	Linseed nuts	37·6
6	Green lucerne	32·6

It will be seen that Lot 2, which shows the least loss in body weight shows the smallest salt lick consumption, while Lot 5, which shows the greatest loss in body weight, shows the greatest consumption of salt lick. The consumption varies from ¼oz. to ½oz. per head per day.

Costs.—In Table XIV. are given the costs of feeding 100 sheep per day at each ration, together with the costs for the experiment, considering lots of 20 sheep for periods of four weeks and a total of eight weeks:—

TABLE XIV.

Lot.	Price of Feed.	Cost 100 Sheep Day.		Cost for 20 Sheep for four Weeks.		Total Cost for 20 for eight Weeks.
		1st Ration.	2nd Ration.	1st Ration.	2nd Ration.	
		s. d.	s. d.	s. d.	s. d.	£ s. d.
1	Chaff, £1 12s. 6d. per ton	2 0	2 0	11 2	11 2	1 2 4
2	Oats, 1s. 6d. bush.	3 6	4 5½	19 8	24 11	2 4 7
3	Ensilage, 10s. per ton	1 10	2 4½	10 4	13 3	1 3 7
4	Ensilage, 10s.; bran £5 17s. 6d. per ton	2 8½	2 10½	15 3	16 3	1 11 6
5	Linseed nuts, £14 per ton	4 0	4 2	22 6	23 6	2 6 0
6	Lucerno, 17s. per ton	2 3	2 0	12 9	11 2	1 3 11

In compiling the above costs the amounts of chaff and of ensilage not consumed have not been considered. These amount to chaff, 248lbs., = 3s. 7d., and ensilage, 101lbs., = 5d.

CONSIDERATION OF RESULTS WITH SPECIAL REFERENCE TO MAINTENANCE RATION UNDER SOUTH AUSTRALIAN CONDITIONS.

According to Wood (7) the maintenance ration per week for a sheep of 130lbs. live weight under English conditions is:—Dry matter, 28.5lbs.; starch equivalent, 10.5lbs.; protein equivalent, 0.50lbs. Allowing that the sheep in this experiment satisfied their appetites on the wheat straw available, the rations supplied would fall short of supplying the maintenance requirement of carbohydrate, and the sheep should lose weight to the extent of that shown in Table XV.

In this table is shown the mean loss of fat per week calculated from Wood's (7) figures, together with the actual mean loss in weight as obtained by weighing of the experimental lots.

TABLE XV. •

Lot.	Calculated Mean Weekly Loss in Weight in Lbs.	Actual Mean Weekly Loss in Weight in Lbs.
1	1.6	0.87
2	1.0	0.075
3	1.7	0.79
4	1.8	0.81
5	2.3	1.34
6	2.3	1.04

It appears that the maintenance standard as given by Wood (7) under English conditions is too high under general South Australian sheep feeding conditions by the equivalent of approximately 1lb. of fat per week.

Hand-feeding of sheep in South Australia is generally necessary at the end of summer and during autumn when temperatures are generally high.

The average maximum temperature for February and March is between 80 and 90 degrees. Under these climatic conditions very little food would be required for maintaining body heat as compared with English conditions.

This would explain the lower carbohydrate maintenance requirement obtained from this experiment.

SUMMARY AND CONCLUSIONS.

1. An experiment in the supplementary feeding of sheep was carried out with six lots, each of 20 pregnant ewes. Of these 10 were Merino and 10 Dorset Horn-Merino half-bred ewes. The experiment commenced on February 22nd, after allowing one week for the animals to become accustomed to the experimental conditions, and covered a period of 15 weeks ending on June 8th. From the point of view of actual gain or loss of body weight the experiment finished on April 19th, a period of eight weeks.

2. The feeds tested were chaff, oats, ensilage, ensilage plus bran, linseed nuts, and green lucerne. The rations fed were each calculated to contain a maintenance requirement of 0.50lbs. of protein equivalent per sheep per week. Each lot was enclosed in a 2-acre plot of long wheat straw stubble which had been previously grazed.

3. "Toxaemia of Pregnancy Disease" (T.P.D.) or "Twin Lamb Disease" (T.L.D.) occurred in all lots except those fed on ensilage alone.

After access to stubble feed was cut off a ration of 2lbs. 10ozs. of green lucerne per head per day failed to prevent the occurrence of T.P.D. The lot fed on ensilage alone, although similarly cut off from stubble feed at the same time, did not show any cases of T.P.D. Because the number of ewes carrying twin lambs—most susceptible—was few the non-appearance of T.P.D. cannot be stated as directly due to the ensilage ration. A further experiment using a larger number of sheep is necessary to test the effectiveness of feeding large quantities of ensilage to prevent an outbreak of T.P.D.. Although nine cases of T.L.D. occurred in the 120 experimental ewes being hand-fed, only one case—triplet lambs—occurred amongst the remaining 323 pregnant ewes on the property which did not require to be hand-fed.

4. Oats alone showed the least loss of weight. Cases of T.P.D. occurred first in lots fed on oats and ensilage plus bran respectively.

5. The outbreak of T.P.D. followed a period of low maximum temperatures, and generally cold conditions following after rain. The necessity for well-sheltered lambing paddocks is indicated by this.

6. Of the nine cases occurring five showed less mean loss, while four showed a greater mean loss in weight than the mean loss of the 10 ewes of the same breeding and on the same feed.

7. If the appearance of T.P.D. is not considered, then on the basis of the values shown, oats showed the best result, but at the highest cost. As far as body weight was concerned, a good sample of chaff did not show any significantly different result from ensilage and ensilage plus bran and green lucerne. There was little difference between the cost of chaff, ensilage, and green lucerne, but ensilage plus bran was more costly. While cereal ensilage plus a concentrate gave no better results than chaff as far as body weight is concerned, the value of ensilage for ewes with lamb at foot has not been assessed. The value of ensilage in this regard may be much greater than a dry feed, for apart from helping the ewe before lambing, by maintenance of good body tone, its succulence would assist the ewe very materially in maintaining adequate milk supplies in the absence of greenfeed.

8. For the whole series the Dorset Horn-Merino half-bred ewes responded better to hand-feeding than did the Merino ewes.

9. At this period of the year pregnant ewes will consume from $\frac{1}{4}$ oz. to $\frac{1}{2}$ oz. daily of the salt lick supplied.

10. It appears that the maintenance standards published abroad are too high under general South Australian sheep-feeding conditions by approximately the equivalent of 1 lb. of fat per week. This is most probably due to more favorable temperatures and general climatic conditions.

Acknowledgements.—My thanks are due to Dr. A. R. Callaghan, Principal, and Mr. A. R. Hickinbotham, Lecturer in Chemical and Physical Sciences, for their helpful suggestions and kind assistance, which enabled me to carry out this work and to report on the same.

SOUTH AUSTRALIAN COMMITTEE OF AUSTRALIAN DAIRY COUNCIL.

SOUTH-EASTERN PASTURE COMPETITION, 1933.

This year another pasture competition was arranged for dairymen who milked not less than seven (7) cows in the South-Eastern districts.

Nine (9) entries were received, and these were judged between November 24th and December 6th by Mr. E. S. Alcock, Agricultural Instructor for the South-Eastern District. The soil type varied from light, sandy, and volcanic loam to the reclaimed peaty soils from Rendelsham and Robe.

Density of Sward.—With such a variation of soil type it was only natural to find some variation in the sward of pastures. On the lighter soils, subterranean clover and Wimmera rye grass gives an excellent pasture, whilst on the lower lying, peaty soils strawberry clover, black medic, white clover, and perennial rye grass are all suitable.

Quality of Pasture.—In this connection more attention could be given to frequent grazing or cutting of pasture. In this way the feed is not allowed to grow away from the animals, and thus become long, rank, and unpalatable.

Freedom from Useless Plants.—These can be controlled provided the pasture is carefully fertilised and grazed, and also by the use of the grass mower at certain times of the year. Phosphatic manures stimulate the growth of legumes such as clovers, &c. Nitrogenous manures increase the growth of the grasses. It will be found easier to establish grasses in a paddock that has carried clover for several years, because the legumes are able to extract the nitrogen from the air and store it in the soil for the use of the grasses.

General Management.—Under this heading more attention can be given to systematic grazing, so that new growth is developed over the largest period possible. Top dressing needs to be carefully carried out, and the fertiliser regularly distributed over the surface of the ground, thus promoting an even growth of pasture. Large fields should be subdivided so that they may be grazing in rotation, whilst the planting of suitable trees for shade and shelter, together with the provision of adequate water supplies, are matters requiring recognition if full pasture returns are to be secured.

Area.—Points have been awarded on the following basis according to the area submitted:—2 points for each 5 acres or portion thereof, with a maximum of 10 points. Therefore not less than 25 acres are needed to secure maximum points under this heading.

The points awarded to each competitor are shown in the following table:—

STAR THISTLE (*Centaurea calcitrapa* L.)

A. One of the individual flowers of which the "head" is composed.
 B. A "head" or thistle, in fruit, showing the formidable involucral bracts—hence the comparison to calthrops.
 C and D. Two extreme forms of involucral bracts.
 E. Seeds.

SAFFRON THISTLE (*Carthamus lanatus* L.).

1. Stem-clasping leaf. 2, 3, 4, 5. All stages, from a floral leaf to a bract. 6. Individual florets.
 7. Anther showing bristly appearance at upper part of filament. 8. Fruit, crowned with the pappus and the remains of a floret. 9. Extreme forms of the scales of the pappus.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

NOS. 2 AND 3.—THE STAR AND SAFFRON THISTLES.

(*Centaurea Calcitrapa*, L., and *Carthamus lanatus*, L.)

In view of the confusion which exists with regard to the two above-mentioned thistles, it is proposed to deal with them together in a single descriptive article, and, in accordance with a suggestion made by the Director of Agriculture (Professor A. J. Perkins), the two have been illustrated in color on the one plate, the figures being adapted from black and white drawings of the two plants in the late Mr. J. H. Maiden's "Weeds of New South Wales."

Both plants are easily recognisable in the field, the Star Thistle by its bushy spreading habit and very numerous heads of pink or purple flowers, the Saffron by its more erect mode of growth, its greater rigidity, and by the fewer and larger heads, the individual florets of which are yellow in color. Unfortunately, the latter plant has been referred to at times as the Star Thistle, and so has come to be known to a good many farmers by a name which really belongs to an entirely different species. It is difficult to trace where this error originated, but much of the present-day confusion is due to the unfortunate wording of an Act of Parliament, passed by the Legislature in 1887 with the object of preventing the further spread of *Carthamus lanatus*, the plant being referred to, however, as the Star Thistle. Not that the misnomer was entirely without a beneficial result; for, though not intended for *Centaurea Calcitrapa*—the Star Thistle proper—the wording of the Act was such that it applied to both thistles, a state of affairs by no means undesirable, since both weeds were equally objectionable at the time.

Another factor tending to create confusion is that, from the point of view of aptness, the name "Star Thistle" can be applied equally well to either plant. In both the flower-head is surrounded by an involucre composed of a number of whorls of sharp-pointed leaves or bracts, suggestive of a star. One of the great difficulties associated with the use of vernacular names for plants is the paucity of adequately descriptive names as compared with the large number of species requiring them. It is manifestly impossible to name several thousand specifically distinct plants from a vocabulary of a few hundred terms, many of which are based upon characters common to a dozen or more species. Such names as "Milk-weed," for example, might seem to be eminently suitable for plants with a milky sap; but when it is realised that this character is present in many different species, belonging to widely different families, and with fundamentally different properties, the inadequacy of such a name for any one plant becomes at once apparent. Star-like formations of leaves or bracts are by no means uncommon, even within the thistle family, so that the name "Star Thistle" might be given to any one of a number of such forms without erring against descriptive accuracy. Actually, however, this name has come to be applied and belongs to certain species of the botanical genus *Centaurea*, and especially to the purple-flowered *Centaurea Calcitrapa*, which is so common along the roadsides during the summer months.

To refer to the *Carthamus* as the "False" Star Thistle in contradistinction to the "True" Star Thistle, is obviously an attempt to compromise with usage having its origin in confusion between the two plants. The name "Woolly Star Thistle" is also open to the objection that, despite the specific name *lanatus*, many specimens

of Saffron Thistle are not noticeably woolly. The use of such adjectives seems, to the writer, to obscure rather than to clarify the position, and so, throughout the remainder of this account, *Carthamus lanatus* will be referred to as Saffron Thistle.

The Thistle Family.—The thistles constitute a relatively small group of plants, which belong, however, to one of the largest of the families of flowering plants. This family, which comprises about 900 genera, with over 13,000 species—more than one-tenth of the total number of flower-bearing species—is, none the less, one of the best defined and most easily recognisable of the entire series. It is the family *Compositae*, and derives its name from the compound or “composite” nature of the flower-heads, structures with the outward appearance of single flowers, but composed, in reality, of a variable number of minute flowers called “florets,” all aggregated together to form a compound inflorescence. Such is the type of floral structure present in Sunflowers, Chrysanthemums, Capeweed, Thistles, Dandelions, and all other representatives of the family. The single flowers of other families are usually protected in the bud stage, each by a whorl of leaf-like structures, called the calyx of the flower; in the aggregation of flowers making up the head of *Compositae*, the calyces of the individual florets are either undeveloped, or represented by scales or hairs, frequently appearing late, and then forming a structure, called the pappus, assisting in the dispersal of the seed or fruitlet. The entire flower-head, however, is surrounded by a number of whorls of leaf-like bracts, forming an involucre, which covers and protects the head during its early stages, the involucre thus serving the same purpose, in the case of the compositous flower-head, as the calyx of a normal flower. It is on account of its star-shaped involucre of sharp-pointed bracts that *Centaurea Calcitrapa* is called the Star Thistle.

Another character of the Composite family—and one of some practical importance—is the development of the individual florets of the head in succession. The single flowers of other families ripen their seeds at the same time, so that such plants are prevented from seeding if they are cut down when in flower. But in *Compositae* the florets are of different ages in the same head, the outer ones being considerably older than those nearer the centre. In the one head some florets will have set seed, while others have not even opened, and viable seeds (fruitlets) may be liberated, when dry, from plants which were hoed out at what seemed to be an early flowering stage.

The thistles are not, strictly speaking, a botanical group. They are more or less spiny plants belonging to one of the 13 tribes into which the family *Compositae* is subdivided. This tribe, the *Cynare*—so called from the contained genus *Cynara*, of which *C. Scolymus* is the true Artichoke and *C. Cardunculus*, the Cardoon or Wild Artichoke—includes a large number of species, many of which possess a bristly or spiny involucre, as well as being spiny, sometimes, on the leaves and stems. Such plants are thistles proper; but many *Cynareae* are not spinescent, and, in fact, the same genus may contain both thistles and non-thistles. The garden Cornflower, for example, is not a thistle, even though it answers to the botanical name *Centaurea Cyanus*, and belongs to the same genus as the Star Thistle. Sometimes other plants are referred to, loosely, as thistles. These may be members of other tribes of *Compositae*, like the Sow Thistle (*Sonchus oleraceus*), or they may belong to quite different families, as is exemplified by such names as Russian Thistle and Yellow Thistle, applied to species of the Saltbush and Poppy families respectively.

THE STAR THISTLE (*Centaurea Calcitrapa*, L.).

Botanical Name.—*Centaurea* is named after the Centaur Chiron, the legendary father of medicine, who, according to Greek mythology, was supposed to have used some such plant to cure the wound in his foot, caused by the arrow of Hercules. The Romans distinguished between a Greater Centaur and a Lesser

Centaurea, two plants which they regarded as being of medicinal value. The former was most probably a species of *Centaurea*, while the latter was the plant known as Common Centaury—often corrupted to “Century”—*Erythraea Centaurium*, L., a small plant with red flowers belonging to the family *Gentianaceae*. *Calcitrapa* (from L. *calx*, *calcis*, a heel, and *trappa*, a snare) is the same word as Caltrop. The caltrop of the Roman soldiers was a round ball with four iron spikes so disposed that, three of them being on the ground, the other pointed upwards, and was thrown under the feet of the horses during a hostile cavalry charge. The spiny involucre of the Star Thistle is suggestive of a miniature caltrop.

[Botanically, the Caltrop is *Tribulus terrestris*, a small prostrate plant with pinnate leaves and spinescent fruitlets, somewhat like those of a Three-corner Jack, and, like them, capable of penetrating and wounding the feet of animals. This plant is quite unrelated to the Star Thistle.]

Description of the Genus.—The genus *Centaurea* comprises between 300 and 500 species, belonging mostly to Europe, northern Africa, and Asia. Several other species are introduced weeds in the State, e.g., *C. solstitialis*, the Yellow Cockspur, and *C. melitensis*, the Maltese Cockspur, both of which are thistles; *C. nigra*, Knapweed, and *C. repens*. The latter is a perennial with an underground stem, and is difficult to eradicate.

The *Centaureas* are herbs with entire or pinnatifid leaves, seldom prickly, and with purple, blue, or yellow flowers. The involucre is globular or ovoid, the bracts numerous, ending either in a prickle or in a fringed or toothed appendage. The outer florets are usually larger than the other, and neuter. The receptacle has soft bristly hairs between the florets; the fruitlets are smooth, and bear a pappus of simple hairs or scales, or none.

Description of the Species.—*Centaurea Calcitrapa* is a coarse green bushy annual, or sometimes biennial, 1ft. to 2ft. high, more or less pubescent or slightly woolly. Stems rather slender, pale-colored, with numerous spreading branches, sometimes forming runners. Lower leaves deeply divided, with lanceolate toothed segments, and, in young specimens, often prostrate, the contiguous segments of adjacent leaves forming a series of flat concentric circles, and giving to the young plants a peculiar cob-webby appearance; stem-leaves pinnatisect with slender lobes. Flower-heads rather small, numerous, purple or pink, sessile among the upper leaves, or in the forks of the branches. Involucre of several rows of bracts, the middle ones ending each in a stout yellow spine, $\frac{1}{2}$ in. to 1 in. long, with 4 to 6 spinules arranged pinnately at the base; or the involucre may be barren and the bracts entire, and $\frac{1}{2}$ in. to 1 $\frac{1}{2}$ in. long. Fruitlets without a pappus, streaked with brown. Period of flowering: November to January.

Properties.—The Star Thistle is entirely useless; it is of no value as a fodder, either fresh or as ensilage, and its prickly growth hinders the movements of animals and covers the ground to the detriment of other herbage.

THE SAFFRON THISTLE (*Carthamus lanatus*, L.).

Botanical Name.—*Carthamus* (from Arabic *quartam*, to paint) is in allusion to the dyes obtainable from the flowers of the best-known species, *C. tinctorius*, L., the Safflower, or False Saffron plant of India. The species name *lanatus* (from L. *lana*, wool) is on account of the woolly appearance of some specimens of the thistle. A synonym for the plant is *Kentrophyllum lanatum*, DC. (Gr. *kentron*, a spine, and *phyllon*, a leaf, alluding to the sharp-pointed leaves).

The Genus Carthamus.—There are about 25 species of the genus belonging to the Mediterranean region, northern Africa, and Asia. They are annual plants, and are characterised by their spiny leaves, and also by having the flower-heads surrounded by a number of whorls of rigid spiny floral leaves outside the involucre

proper. The most important economic species is the Safflower (*C. tinctorius*), which is cultivated in Asia for its flowers. These contain a red dye known as carthamine, insoluble in water, and also a soluble yellow pigment, saffron-yellow. The former is the basis of a rouge, prepared by mixing the dried and powdered flowers with talc. The latter is used as an adulterant of, or as a substitute for the true Saffron (*Crocus sativus*, L.). Apart from *C. lanatus*, the only other species in this State is *C. glaucus*, an introduced thistle very similar to the Saffron, but with blue instead of yellow flowers.

Description of C. lanatus.—A stiff, minutely pubescent, and sometimes woolly annual, growing to a height of 1ft. to 3ft.. Stems pale-colored and rigid, at first erect, then becoming branched from about the middle upwards, the branches terminating in yellow flower-heads with a number of whorls of floral leaves surrounding and concealing the involucre proper. Leaves tough and rigid, dark-green in color, and very prominently veined, almost stem-clasping at the base, and pinnatifid into slender, rigid, and pungent lateral and terminal lobes. Floral leaves resembling the stem ones, but passing insensibly into the lanceolate, rigid, and sharp-pointed involucre bracts. Receptacle with soft bristles between the individual florets, which are all tubular and usually fertile, and longer than the involucre proper. Fruitlets smooth, mostly 4-ribbed, flattened on the top, about $\frac{1}{4}$ in. long, and with a pappus of short, slender scales. In flower: November to December.

Properties.—Despite its toughness, the Saffron Thistle is said to be eaten by stock to some extent, especially in the seedling stages and in the form of ensilage. The claim has also been made that, by opening up the ground it allows moisture and air to enter, and so has a beneficial effect on the soil, and further, that a dense growth of the thistle prevents the ground from being denuded of herbage by summer winds, and favors a more luxuriant growth of grasses after the first autumn rains. But any such advantages as these are trivial in comparison with the harm done by the weed when allowed to grow unchecked. The mature growing plants are useless as fodder, and cover the ground with a prickly growth liable to cause injury to sheep and other animals. The plant seeds very freely, and is difficult to suppress unless very determined measures are taken against it before it comes into flower.

ERADICATION OF STAR AND SAFFRON THISTLES.

Both thistles are annual plants, and can be got rid of so long as they are prevented from forming seeds. As has been pointed out above, the seeds (fruitlets) of thistles are formed *successively* in the flower-head, so that the only certain way to prevent them from maturing is to cut down or otherwise destroy the plants *before* (not *during*) the flowering stage. Thoroughness is essential in such operations, and much labor may be wasted if some plants are allowed to escape, or if control measures are undertaken too late. But if the methods are conscientiously and, if necessary, repeatedly practised, there should be no difficulty with either of these thistles, provided that concerted action along the same lines is undertaken by neighboring landowners, district councils, and others concerned. In the case of the Saffron Thistle the plants retain their rigidity, even when dry, and so may be a cause of injury to grazing stock after they have been cut down. They should therefore, be burned, if possible, as soon as they are sufficiently dry.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT
PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 3 parts wholemeal (by weight), ½lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), ½lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), ½lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 5 Test.—Morning—1½ozs. wheat per bird.

Evening—1½ozs. wheat per bird.

Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to January 31st, 1934.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

No. of Test.	No. Eggs Laid April 1st to December 31st.	No. Eggs Laid Month January.	Total Eggs Laid April 1st to January 31st.
No. 1	5,650	668	6,318
No. 2	5,262	695	5,957
No. 3	4,794	614	5,408
No. 4	5,537	767	6,304
No. 5	2,524	333	2,857

BLACK-EYED SUSAN, OR ROCK LILY—*Ornithogalum thyrsoides* (Jacq.).

[By A. L. WARREN, R.D.A., Field Officer.]

Black-Eyed Susan, or Rock Lily, belongs to the Lily family (*Liliaceae*), which is well represented in all parts of the world, and is most abundant in the temperate regions. A number of species are cultivated as vegetables, the shoots of asparagus and the bulbs of onions being familiar to all. Not a few are valued ornamental plants, such as the tulips, hyacinths, and many showy lilies; whilst a few contain poisonous properties, the effect being purgative, emetic and narcotic. Some of

Black-Eyed Susan or Rock Lily
Ornithogalum thyrsoides (Jacq.).

these are of use in medicine. On account of the property of tainting milk and meat, owing to the unpleasant garlic-like smell possessed by several naturalised species, they are bad weeds of both pasture and arable land.

The lilies are sometimes *arborescent* shrubs, but in temperate regions are mostly fleshy herbs, often with underground bulbs, or rhizomes. The roots are mostly shallow, but sometimes extend to considerable depths in the soil. Bulbs, root-stocks, and rhizomes are storage organs which, through being buried in the soil, are well protected, and plants so provided are most difficult to control or eradicate.

The leaves are usually long, simple, parallel-veined, and often sheathing the stem. Flowers mostly several, in spikes, panicles, or umbels, always with bracts. They are regular, perfect, conspicuous, with a perianth of six divisions, either free or united towards the base, usually arranged in two rows. Stamens are six in number, inserted at the base of the perianth; ovary superior, three-chambered; fruit, a berry or capsule.

The genus *Ornithogalum*, to which the Rock Lily belongs, is a large and well-known ornamental one, with a perianth of six segments, which are spread in the form of a star. Most of them are native to the Mediterranean region, or South Africa, and South Africa is the original home of *O. thyrsoides*. Members of this genus are not provided with the objectionable odor so characteristic of garlic. The bulbs of some species, when cooked and eaten, are said to be wholesome and nutritious. Nevertheless, when they spread out of control, they would be undesirable weeds, because they have no forage value, and choke out useful herbage. Also, they have ample provision to reproduce themselves both by means of numerous seeds and bulbs.

Two species of *Ornithogalum* have been recorded for South Australia:—

(1) *O. arabicum*, which has not established itself to any extent.

(2) *O. thyrsoides*, which has within the last few years spread over a small area near the Abattoirs, and in the Hills, at Horsnell's Gully. Near the Abattoirs it is inhabiting open country, which has in the past been cultivated. Here it has followed a slight depression in the level of the ground, from the main road towards the sea. In Horsnell's Gully it is occupying a very steep, stony, and almost inaccessible hillside, and although isolated patches occur on both sides of the valley, it does not appear in any of the cultivated land.

The history of the Rock Lily at the Abattoirs is obscure, but in the Hills it has been known to exist for many years, where it has apparently spread from an old garden, which was established in the early days of the State, and it has not covered much new ground during the last twenty years, so that it may be concluded that it is a garden escapee, which will not cause much damage in soils which are regularly cultivated, and that it will only be harmful by crowding out useful plants on pasture land.

The common name of Rock Lily has been given to *Ornithogalum thyrsoides* because it is able to maintain itself in very rocky situations, making a handsome display in places which would otherwise be comparatively devoid of herbage. Sometimes it is called Black-Eyed Susan, on account of the brownish blotch at the base of each perianth segment; but this name is more commonly applied to *Ornithogalum arabicum*. *Ornithogalum thyrsoides* is a bulbous perennial, with 5 to 8 long, fleshy, radical leaves, 6in. to 12in. in length, and 1in. to 1½in. wide. The stem, or scape—simple, erect, 12in. to 18in. long, raceme 30-50 flowered, pedicles erect, lengthening after flowering, each with a large, acute scarious bract at the base. Perianth segments ¾in. long, spreading, acute, self-colored, with a brownish blotch at the base. Filaments alternatively longer and lanceolate. Pistil inconspicuous, thus distinguishing it from *O. arabicum*. Fruit—a capsule, with many small irregular black seeds, each capsule containing about 40 seeds.

Unlike many bulbous plants, bulbs are not produced, and there is generally one bulb to each plant, and multiplication will mainly be by seed. The seeds, being small, compact, and without appendages, would not be easily carried great distances; therefore the spread to new areas would be slow. The bulbs being just below the surface of the soil, and without numerous small bulbils, ordinary tillage would facilitate eradication. This should be done before the plants reach the flowering stage. In situations where, for a variety of reasons, tillage is not possible, spraying with a 10 per cent. solution of sodium chlorate should prove effective. This operation should be carried out as soon as there is sufficient growth on the plant to hold the material.

MOUNT GAMBIER AGRICULTURAL BUREAU AND AGRICULTURAL AND HORTICULTURAL SOCIETY'S SIXTH ANNUAL CROP COMPE- TITION.

[Judged by E. S. ALCOCK (District Agricultural Instructor).]

CLASS 4—IMPROVED PASTURE COMPETITION, 1933.

The season which was not quite so favorable for the growth of vegetation as last year opened well with good autumn rains, but the winter months were much drier and colder than usual, and growth in the pastures was also shorter. Spring rains were rather light, and hot winds and frost at the end of October ripened the annual plants on the lighter land. Dry weather also affected plants on the heavier land. These conditions favored the development of the larvae of the cockchafer beetles, and they did considerable damage to many pastures. Lucerne flea was also plentiful in the district.

So far the only practical method of checking the larvae of cockchafer beetles is to break the land early in the season, either before or just after the first rain. If done before rain, the grazing capacity will not be reduced to any great extent, provided the field has been sown with annual plants. Where paddocks have been down to Subterranean clover for several years, the grubs appear in gradually increasing numbers until they reach their maximum. Where they are noticed—if the land is broken up early and then either sown down with oats or other crops—they can be checked. Ploughing destroys or exposes them to their natural enemies, or makes conditions unsuitable for them for a few years.

The pastures entered were all excellent entries, demonstrating the value of sowing suitable forage crops. Mr. Button's New Zealand Certified Perennial rye grass (mother seed) stood out as the best rye grass paddock in that district.

The suitability of Wimmera rye grass and subterranean clover for the lighter soils of this district could also be seen on Mr. W. K. Chambers Dairy Council plot at Mil Lel, and more of this rye grass will be used in future in those areas which are ploughed every few years in order to grow oats, barley, potatoes, &c.

Where weeds grow so prolifically, care and good management are necessary to keep them under control. Competitors sow suitable seeds, and provided their pastures are carefully grazed and adequately top dressed, the pasture plants will crowd out useless plants. Attention might be given to the provision for more shade and shelter for livestock. In this direction, Mr. Caine is to be commended for the work he has done, especially in such a district as Kongorong where cold winds are very severe.

Four entries were received, and these were judged on November 20th and 21st. The details of judging are shown in the following table:—

Name and Address.	Bulk of Pasture Available per Unit of Area.	Quality of Pasture.		Freedom from Useless Plants.	General Care of Pasture.	Area.	Total
		Type of Plants.	Feeding. Value.				
	30	15	10	20	15	10	100

THE PASTURES.

1. F. W. Button, Yahl, 26½ acres. No. of section, 1200. Hundred of Gambier. Three paddocks well fenced and watered; 6½ acres sown with New Zealand perennial rye grass and subterranean clover May, 1932; top dressed with 100lbs. 45 per cent. super annually.

This fine paddock had been well grazed throughout the year, and was in excellent condition. Clean and free from weeds. A good sole of rye grass was established on 6½ acres with 4bush. of certified seed or about 12lbs. per acre.

The other two paddocks had been sown with subterranean clover in 1926 and 1928, also white clover and perennial rye grass. In 1930 3cwt. crushed limestone per acre were applied. The area treated with the limestone produced earlier feed, and was also liked by the stock. Subterranean clover provided the bulk of the grazing of these paddocks with a little perennial rye grass, barley grass, sterile brome, patches of cape weed, and a few thistles. The entry presents a fine sight when compared with many other fields in this district.

The paddocks were harrowed on March 20th and then top dressed. Twenty-three milking cows have been pastured, mainly on the 26½ acres. On September 1st five more cows were brought in, and on October 20th three more head, making a total of 31 cows. The herd had occasional access to a 15-acre paddock.

Portion of Mr. Button's herd on his Pasture Competition entry, which has been kept closely grazed throughout the season.

They received some chou moullier and grass hay until the grass was well started on May 17th. The returns which Mr. Button supplied are very interesting:—

	Gallons of Milk.	Average Test.	Lbs. Butterfat.
1932.		3/3	
December	15-632	3-9	610
1933.

November	23-166	3-9	903
Totals	189-168		7,557

2. F. C. Caine, Kongorong, 25 acres. Section 441, hundred of Kongorong.

This paddock, which was awarded first place last year, was sown in 1928 with subterranean clover, white clover, alsike clover, cocksfoot grass and Western

District perennial rye grass, and has been regularly top dressed with 90lbs. 48 per cent. super annually, except last year, when blood and bone manure was used. This year the paddock received 90lbs. 45 per cent. per acre. The pasture consisted mainly of subterranean clover, sterile and soft brome, a fair amount of perennial rye grass and Yorkshire fog, some cocksfoot rib grass, little slender clover, cape weed, brixia, sorrel, rooted catsear, and white clover in patches. Although very clean and free from thistles and other weeds, rather too long and rank to be a good pasture.

Sufficient use was not made of this earlier in the year, the grazing records show that it was grazed with another 35-acre paddock by 30 milking cows. The grazing results and returns of these two paddocks are given below:—

1933.		1933.	
January	300lbs. butterfat	July	830lbs. butterfat
February	260lbs. "	August	900lbs. "
March	320lbs. "	September	1,050lbs. "
April	420lbs. "	October	1,150lbs. "
May	530lbs. "	November.....	1,020lbs. "
June	680lbs. "		

Total, 7,460lbs. butterfat.

3. F. C. Caine (2), Kongorong, 35 acres.

Mr. Caine's entry in the Pasture Competition lost points on account of its rankness of growth and of insufficient stocking.

Sown with the same mixture as the previous paddock, and top dressed in a similar manner. Mainly subterranean clover, sterile brome, soft brome, perennial rye grass, cocksfoot, silver grass, a few slender thistles, and white rushes. The majority of the plants were more matured in this field, for it did not appear to have been grazed so heavily except around the gate, where the feed was much shorter and greener.

These paddocks provide an interesting example of pasture improvement, and Mr. Caine is to be congratulated on the work he has done. However, judging by the appearance of his fields, he could carry much more stock than he does.

4. E. J. Byrne, Glencoe East, 11½ acres. Part section 102, hundred of Young.

Two paddocks sown with 26lbs. perennial rye grass, 2lbs. white clover, 1lb. strawberry clover, 1lb. subterranean clover in 1930 with an oat crop. The seeds were broadcast by hand after the oats were drilled, then top dressed with 90lbs. 45 per cent. super annually, except in 1932.

The second paddock was sown a year later. A good entry on rather light land, consisting of perennial rye grass, Yorkshire fog, subterranean clover, slender clover, little white birdseye, and knotted clovers, sterile brome and brixia. These paddocks should provide a good picking for the 16 cows grazing on them for a good part of the year. Although growth was rather long and somewhat rank when inspected, it was intended to run the mower over it. The pastures were also very clean and free from weeds. A good entry showing what improvement can be effected with light land.

VARIABILITY IN STOCK-POISON PLANTS.

(*Peculiarities in the behavior of certain plants with regard to their poisonous properties under changed conditions of climate, soils, localities, &c., are discussed in an article by F. N. Howes in Bulletin No. 7, 1933, of the Royal Botanic Gardens, Kew. Apart from its scientific value, the bulletin is of more than usual interest to livestock owners, and much of the information contained in it may apply to conditions within our own State. Extracts of the article are published below.*)

Continuous overstocking does much to increase the incidence of plant poisoning, for animals are then prone to consume unwholesome or harmful plants, which, under more normal conditions, they would not touch. Overstocking frequently results in a steady diminution in some, if not all, of the more desirable species while others (which may be toxic) gradually increase.

With improved stock the possibility of vegetable poisoning assumes a more serious aspect and deaths resulting therefrom involve greater financial loss. Low grade native stock require considerably larger quantities of certain poisonous plants to produce fatal results than do well bred animals. Imported animals are often less discriminating than those locally bred and may consume harmful plants that are left untouched by other animals.

Losses appear to be greatest in the more arid subtropical parts of the world. In parts of South Africa, Australia, and the South-western United States of America, the aggregate mortality is without question higher and of greater seriousness than in pastoral regions in temperate countries. In some areas of the United States the annual losses due to poisonous plants are regarded as being considerably in excess of those caused by infectious diseases or by predatory animals.

It is in arid or semi-arid areas, where the vegetation is subject to unusually varied climatic and edaphic conditions, with irregular rainfall and often prolonged conditions of drought, that the question of variability in toxicity among poisonous plants (*i.e.*, variability in the same species) is becoming so apparent.

Intensive experimental work has been, and is being, carried out on stock-poisoning plants in various countries, especially South Africa, Australia, and several parts of the United States. Diagnosis in vegetable poisoning is often complicated by the fact that the symptoms produced by some plants are closely similar to those caused by certain bacterial diseases or other pathological disorders. It is believed by veterinarians and others that many of the obscure affections of livestock that at present baffle solution will eventually be traced to plant agency. Some species of poisonous plants affect the animal in a distinctive and characteristic manner, the effects being quite unlike those produced by other poisonous plants. On the other hand different species occurring in different countries may cause a strangely similar type of poisoning. This is becoming increasingly noticeable among plants whose toxicity is of the cumulative type, *i.e.*, where poisoning does not take place until a fairly large quantity of the plant has been consumed continuously over a lengthy period which may extend to several weeks or months.

Among the several factors liable to influence the toxicity of poisonous plants two of the most important have been shown to be the season of the year when consumed and the area where grown. Seasonal variation in toxicity has now been closely studied in a number of troublesome plants and some interesting facts ascertained.

sheep, is only toxic during some two or three months of the year. Another

In South Africa, *Tribulus terrestris* L., the cause of a serious malady with plant (*Pachystigma pygmaea* Schltr.) Robyns, is responsible for a sheep disease

and is known to vary a great deal in toxicity from season to season. In some seasons the disease is quite absent whereas in others mortality is high. Another sheep disease, prevalent in drier areas, has been shown to be due to grazing on certain species of *Geigeria*, among which are *G. passerinoides* Harv., *G. aspera* Harv., and *G. Zeyheri* Harv. These shrubs have to be consumed for several weeks before symptoms develop and it has been shown that they vary considerably in toxicity throughout the year. Certain species of *Cucumis*, e.g., *C. myriocarpus* Naud and *C. Africanus* L.f. have been found to be troublesome in sheep in the winter months, but not in the summer in South Africa.

In regions subject to a distinct or pronounced dry season the incidence of plant poisoning is often highest at that period when the dry season finishes and the first rains commence. This may be due to the fact that at this particular period there is a shortage of pasturage and harmful plants not normally eaten are consumed. In these regions it is often found that in seasons when the rains are late mortality is noticeably higher than in normal seasons. A factor which may, and often does, account for this is that the poisonous plants in question may be of a succulent or bulbous nature and not so dependent on the rains for the commencement of growth as are the grasses or other pasturage plants. The result is that the noxious species appear in leaf first and may be eaten in quantity by browsing animals, particularly as herbage is scarce at that period.

The stage of growth when consumed is an important factor with some species in determining whether they are likely to be toxic to animals. Some plants have been shown to be harmful only in the very young stage, others only when flowering or in fruit, and others only when in a wilted condition. Plants poisonous only when wilted or in the young stage frequently owe their toxicity to the presence of cyanogenetic glucosides. Some plants, however, which are poisonous only when very young are not cyanogenetic. *Chenopodium atriplicinum* F. Muell. affords an instance of toxicity in the young stages only. This saltbush is a common herbage plant in parts of Australia and is frequently grazed by sheep with no ill effects. In some seasons, however, it has been strongly suspected as the cause of heavy mortality. Work in Australia now shows that when fairly large quantities are consumed the plant is liable to prove fatal, though only when the plant is in the young stage. *Echinopogon ovatus* Beauv., the "Noogoora Burr" is another Australian plant regarded as poisonous only in the young (two-leaf) stage.

There appears to have been a marked divergence of opinion regarding the danger to livestock of *Lotus australis* Andr., a plant widely distributed in Australia. From material examined at the Imperial Institute it was found that immature plants contained a cyanogenetic glucoside, but fully developed plants contained nothing of a toxic character. This fact no doubt explains the contradictory reports that exist regarding the plant.

In the case of *Dichapetalum cymosum* (Hook) Engl. in South Africa the young growth is considerably more toxic than the old and as little as ½ oz. of the leaves have been proved to be sufficient to cause the death of a sheep. It is unusual among stock-poison plants for such small quantities to constitute a lethal dose. With the bulk of the important stock-poisoning plants of the world, i.e., those that actually cause heavy losses, comparatively large quantities have to be taken by an animal before harmful or fatal results occur. This is contrary to popular belief.

There is increasing evidence to show that plants which are toxic in one area may, although plentiful, be innocuous or but slightly toxic in another. *Tribulus terrestris* L., previously referred to, does not appear to be associated with stock-poisoning in any country except South Africa. Among Australian plants there are several examples of this variation in toxicity attributed to locality. *Euphorbia Drummondii* Boiss., a common weed, has been found to be toxic in some localities, but not in others.

Diseases of sheep in Australia known as "staggers" or "shivers," often resulting in death, are caused by certain alien species that have become completely naturalised (*Stachys arvensis* L., *Malva parviflora* L., and *Lamium amplexicaule* L.). These plants are natives of European countries, but do not appear to have come under suspicion in regard to poisoning in their native habitat. There are also good reasons for suspecting that *Lantana crocea* Jacq. and *L. Camara* L. may vary in their degree of harmfulness to stock in different parts of Australia.

It is reported that in 1891 Russian peasants of Saratov suffered from "lathyrism" as a result of large quantities of a commonly cultivated pulse (*Lathyrus sativus* L.), being imported from India and used in the preparation of bread owing to the shortage of wheat at that time. It is of interest in this connection that in Canada, where *Lathyrus sativus* is cultivated and the seeds used as food, toxic symptoms do not arise.

The succulent *Cotyledon orbiculata* L. or "pig's ear" causes death in fowls and sheep in South Africa. It has been found that the toxicity varies in different areas and this variation is believed to be due to soil conditions.

Generally, the active poisonous principle exists in greater concentration in some particular organ of the plant. In a large number of species the roots or rootstocks are poisonous and there are occasions, such as after heavy rain, when the roots may come away from the soil on the first tug of grazing. Rootstocks may be washed up or exposed along watercourses as is believed in the case of *Cicuta occidentalis* the "poison parsnip" or "water hemlock" in the United States.

The species of animal, its age, and condition are important factors in determining the effect produced on an animal, particularly in the case of prussic acid. Generally speaking young and immature animals are far more susceptible than the older ones.

Feeding habits are sometimes responsible. Sheep are more selective feeders than cattle or horses and often leave plants that are eaten indiscriminately with the other herbage by larger animals. Species of *Ranunculus* when in flower may poison cattle and horses, but not sheep, which are better able to avoid them. Sheep have been recorded as avoiding a plant one day which they may partake of copiously the next. Furthermore some sheep may be observed feeding freely on one species that other sheep in the same flock will avoid. Among animals of the same breed, age, and state of health it has been found that the quantity of a given plant required to kill one animal may be four times as great as that required as a lethal dose for another. One species may be harmful or fatal to one class of animal, but harmless to another. Others may be harmful to more than one class of animal, but produce different symptoms in those respective classes.

The action of *Leucaena glauca* Bth. affords an interesting example of a plant harmful though not fatal to some classes of animal, but harmless to others. In tropical and subtropical countries it is used as a soiling crop, fodder, or hedge plant and the leaves and shoots are readily eaten by most grazing animals, and the plant affords nutritious hay. In the West Indies and elsewhere horses, mules, donkeys, and pigs feeding on the plant lose their hair (in varying degrees), but cattle, sheep, and goats consume it without perceptible effects. It has been suggested that in ruminants the process of mixing the food with saliva and slowly digesting it may cause the poisonous principle to be neutralised, and these animals therefore escape injury.

Numerous instances of immunity in wild animals are known.

The curious effect of certain plants in acting harmfully only on animals with unpigmented skin or those breeds without pigmentation is well known in such plants as *Hypericum perforatum* L., St. John's Wort; *Fagopyrum sagittatum* Gilib., Buckwheat; *Medicago denticulata* Willd., Trefoil Burr; and certain species of *Trifolium*. The ingestion of such plants by stock in sufficient quantity leads to

photosensitisation with the development of dermatitis and later necrosis of the unpigmented surfaces of the body on exposure to sunlight. Those animals in which the exposed parts are pigmented are quite unaffected. Sunshine is necessary for the development of the malady, and if dull weather accompanies or follows feeding of the plant or if animals are kept out of sunshine, symptoms do not appear. Photosensitisation in sheep is due to St. John's Wort, and at one time it was thought that possibly only the mature plant was harmful, but it has now been shown that this effect may be caused in the early stages of growth. Buckwheat has been known to cause the same trouble in various classes of livestock in the United States.

Poisoning from the presence of compounds of hydrocyanic acid in plant tissue is of common occurrence and no doubt occurs more frequently in the *Gramineae*. Species of *Sorghum* have been long known to be liable to contain dangerous amounts of such glucosides and to have been the cause of serious fatality among various classes of stock. It has been found in *Sorghum* and many other plants that danger exists chiefly in the early stages of growth, *i.e.*, during the period of rapid formation of new tissue or when the plants are in a wilted or damaged condition. With most cyanogenetic plants a fairly large quantity of material must be consumed by the animal within a comparatively short time for death to occur. Many pasture plants, regarded as excellent stock feed when consumed under normal grazing conditions, *i.e.*, eaten at intervals and grazed along with other plants, may cause death if eaten extensively in a short period of time.

Certain leguminous plants, normally nutritious fodder plants, may sometimes show evidence of hydrocyanic acid and that this is liable to considerable variation. Among these is the European species *Lotus corniculatus* L., which may be completely devoid of any cyanogenetic substance in one year, but may possess a considerable quantity the next. Stunted drought forms exhibited a more abundant development of the substance than did forms of a more luxurious growth.

Many fodder plants which may be cyanogenetic, such as "Johnson's grass," *Sorghum halepense* Pers., and other species of *Sorghum* are commonly regarded as quite innocuous when dried or made into hay, the cyanogenetic substance being often of an unstable nature and free hydrocyanic acid rapidly disappearing on drying.

Variations in cyanogenesis has now been shown to be a feature of many Australian plants dangerous to livestock. One of the best examples is probably that afforded by *Euphorbia Drummondii* Boiss. This plant has long been suspected among some stockowners in Australia as the cause of death in stock, whereas others have always contended that the plant is harmless. Out of a total of 113 specimens examined from various localities in New South Wales only 11 were found to contain a cyanogenetic substance (hence the diversity of opinion). Certain species of *Acacia* in Australia are also known to be cyanogenetic, but to be devoid or nearly devoid of the requisite enzyme for liberation of prussic acid. Among other dangerous cyanogenetic plants of Australia are *Cynodon incompletus* Nees, "blue couch"; *Heterodendrum oleifolium* Desf., "rosewood"; *Lotus australis* Andr., "birdsfoot trefoil"; *Silybum Marianum* Gaertn., "variegated thistle" (possibly); and *Chenopodium carinatum* R. Br.

The importance of saponins in plants as the cause of several obscure stock diseases in many parts of the world is now well recognised. In the majority of cases it is only by the prolonged ingestion of these saponin-containing plants that injurious results are caused. Other substances such as tannin may completely counteract any ill-effects from the saponin. In parts of Australia *Atalaya hemiglaucæ* F. Muell. causes "walkabout" disease of horses, due to the presence of saponins. Plants quoted in other parts of the world are *Solidago rigida* L., *Solidago canadensis* L., *Aster Parryi* A. Gray, *Senecio Jacobaea* L., *Senecio latifolius* D.C.

Ewart states "Little attention has been paid to the effect of the prolonged ingestion of plants containing saponin upon grazing stock, but it is quite possible that certain obscure diseases of stock, and more particularly of horses, in various parts of the world may be due to this cause."

In Australia "walkabout" disease of horses, due to the "whitewood" *Atalaya hemiglauc* F. Muell. is stated to occur only north of the nineteenth parallel, whereas the tree occurs abundantly down to the twenty-fifth parallel.

Ewart states "Many other cases are known in which a poisonous plant becomes harmless near its southern or northern temperate limit owing to its developing little or none of its poisonous principle under less favorable temperature conditions, and this effect will be increased if the plant under these conditions produces more of a protective substance such as tannin, or forms a variety of the poisonous principle which is more readily decomposed in the alimentary canal."

There are many instances where it is known that deficiencies in the soil of certain minerals result in similar deficiencies in the plants growing in these soils and that these in turn may be responsible for maladies in grazing stock, such maladies being commonly known as "deficiency disease." It is therefore possible that a plant or community of plants may afford a wholesome and adequately balanced stock food in one area, while in another it may, in the course of time, be responsible for a deficiency disease owing to the shortage of a certain mineral under altered soil conditions. The lack in the pasturage of any one of the essential minerals may cause only a mild disorder in the animal, such as unthriftiness or lack of condition if of mild degree, but if of greater intensity it may lead to more grave disorders and to the death of the animal. The insufficiency of such minerals as phosphorus, calcium, iron, and iodine has been shown to cause some of the worst forms of deficiency disease in different areas.

Phosphorus deficiency in pasturage is particularly acute in parts of Australia and southern Africa. It has been found that European grasses growing in Australia have a lower average phosphorus content than when growing in Europe, but are nevertheless markedly richer in phosphorus (when grown in Australia) than are the indigenous Australian grasses.

A common symptom in grazing animals of mineral deficiency in the pasturage is in the development of depraved appetite. In the case of phosphorus this leads to the chewing of old bones and carcass debris, often resulting in carrion poisoning. (In South Australia this subject has been frequently dealt with by Veterinary Officers of the Stock and Brands Department.)

Depraved appetite may develop in stock through causes other than mineral deficiency. In the United States a malady ("loco" poisoning) due to certain species of *Oxytropis* and *Astragalus* does not become manifest until prolonged feeding on the plant has taken place, some animals acquiring such a liking for the plant that they refuse to eat anything else right up to the time of death. "Horses formerly quite gentle become uncontrollable and shy violently at imaginary objects or leap high over some slight obstruction. Generally speaking a "locoed" horse can be neither led nor backed, and when put in motion cannot easily be stopped or turned, but may continue until it runs against a fence or other obstruction." It is stated to be almost impossible to drive in any one direction a flock of sheep that have been "locoed."

From the facts outlined in this article it is apparent the term "poisonous plant" when used in connection with the pasturage of food plants of grazing animals, has come to assume a wide significance. It is now commonly used not only for those species that are acutely poisonous, but also for plants that in any way disturb the health of stock. There can be little doubt that those plants that must be consumed in quantity over a long period before harmful results to the animal appear, which, of course, includes those causing deficiency diseases, are of far greater moment to the livestock industry throughout the world than are the more rapid-acting drastically poisonous species.

ADDITIONS TO THE WEED FLORA OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

- (1) *Ajuga Iva* (L.) Schreb.; an Introduced Species Related to Bugle, *Ajuga australis*, R. Br.

This plant, a native of the Mediterranean region and hitherto unrecorded for South Australia, has been growing for some years at the Roseworthy Agricultural College, where it now covers a few acres of ground on what was at one time the College Sports Oval. That it escaped recognition has been partly due to confusion with another species belonging to the closely related genus *Teucrium*, namely *T. sessiliflorum*, Benth. It has also been due to the fact that, during the earlier part of the year the plants produce more or less imperfect "winter flowers" from which it is impossible to determine the exact form of the corolla, an important character in this particular genus. Specimens in flower of *Teucrium sessiliflorum*

Ajuga Iva.

Ajuga australis.

were found by the writer early in October of last year, and it then became evident that the species growing at the College must be an introduced form, and this was found to be the case when specimens with normal flowers became available during November last.

Botanical Name.—The plant is known botanically as *Ajuga Iva* (L.), Schreb.; *Ajuga* (a, privative, and *jugum*, a yoke), referring to the absence of a distinct posterior lip to the corolla, and *Iva* from the similarity of the odour of the flowers to that of another plant, *Iva axillaris*, which—by a singular coincidence—was recorded for this State only a few months ago.

Botanically the genus *Ajuga* belongs to the same family as that which includes such plants as Sage, Mint, Thyme, Rosemary, and Lavender. This family is called the Labiatae, and derives its name from the lipped or "labiate" condition of the

tubular corolla formed by union of the normally five flower petals. In most Labiates the corolla has two well-marked lips, an upper or posterior, and a lower or anterior. In *Ajuga* the posterior lip is very short or rudimentary, while the anterior lip is long and comprises three well-marked lobes.

Another character present in many members of the Labiate family is an arrangement of the flowers in apparent whorls or clusters at the nodes of an erect scape, the whole forming a more or less leafy spike with the flower-clusters at intervals. This arrangement, which is well seen in such plants as Wild Sage (*Salvia Verbenaca*), Horehound (*Marrubium vulgare*), Pennyroyal (*Mentha Pulegium*), and many others, is, however, by no means universal, and may be subject to variation within the limits even of a single genus, and such, indeed, is the case with the genus *Ajuga*. *Ajuga* comprises some 50 species spread over Europe, Asia, Africa, and Australia, but not present in America. Of the two species endemic in Australia, one, *A. australis*, R.Br., known as "Bugle," is quite common in this State and has the type of flower arrangement referred to. It also shows a marked distinction between the lower or "radical" leaves and the upper or "stem" leaves (see illustrations on the right). *Ajuga Iva* (see illustrations on the left) shows a different type of flower arrangement, the flowers occurring singly in the leaf axils; also there is no clear distinction between radical and stem leaves, all the leaves being more or less alike both in size and shape.

Common Name.—No common name has been found for this species. The name "Bugle" is sometimes applied indiscriminately to any species of *Ajuga*, but strictly it belongs only to those having the flowers in whorls of six or more, which species comprise the section *Bugula* of the genus. Thus the name may be used for *A. australis*, or for *A. reptans*, a weed in pastures in Europe and introduced into America, or for *A. pyramidalis*, which is grown in gardens; but it cannot be applied legitimately to *A. Iva*.

Botanical Description.—A perennial with faintly scented flowers, 2in. to 5in. high, woody at the base, the whole plant villous with white septate hairs; stems at first erect; then ascending and branching from the lower nodes, very leafy above, becoming bare and with longer internodes separating the swollen nodes at the base; leaves opposite, obscurely six-ranked, $\frac{1}{2}$ in. to 1 $\frac{1}{2}$ in. long, $\frac{1}{2}$ in. to $\frac{3}{4}$ in. wide, villous on both surfaces, mostly linear- or oblong-lanceolate and sessile, the margins revolute, entire or with 1 to 5 coarse teeth or lobes towards the summit, the midrib prominent on the under surface; flowers solitary in the axils; calyx about $\frac{1}{2}$ in. long, villous, with 5 triangular-lanceolate subequal teeth shorter than the tube; corolla $\frac{1}{2}$ in. to 1in. long with the anterior lip, villous externally and in the lateral part of the throat, the tube $\frac{1}{2}$ in. long, funnel-shaped, almost glabrous inside except for a ring of cilia near the base, the upper lip truncate and very short, the lower with two narrow obtuse lobes and a large broad notched anterior lobe, purple in color the rest of corolla whitish with purple spots in the throat; stamens 4, in pairs, exserted from the upper lip and arched over corolla, the anterior pair longer than the posterior; filaments ciliate; style shortly bifid, with two flattened triangular antero-posterior stigmatic lobes; nutlets reticulate-rugose, $\frac{1}{2}$ in. long, obovate, curved, with an oval scar on attachment on the concave side two-thirds as long.

The local form differs from the European in having the flowers longer, instead of shorter, than the subtending leaves, and the leaves erect rather than spreading; also, some European forms have the flowers 2 to 4, instead of solitary, in the axils.

Properties.—The plant does not appear to be of much consequence. It is tough and hairy, and probably useless as a fodder. On the other hand there is no record of its having any seriously harmful properties, its chief offence being that it occupies space that would otherwise be available to more nutritious pasture plants. It does not appear to spread rapidly, though forming an abundance of seed-like fruitlets. But, like its Australian relative Bugle (*A. australis*), which has earned some slight reputation as a weed at Naracoorte and certain other parts of the State, it does grow particularly well in dry and arid situations, and for this reason it is desirable to record its presence as a potential weed capable of becoming established in many parts of South Australia.

(The writer's thanks are due to Mr. J. M. Black for confirming the identification.)

(2) Bindy-eye as a Potential Weed on the Adelaide Plains.

Bassia quinquecuspis, F.v.M., var. *villosa*, Benth.

Many people are inclined to suppose that all weeds are alien plants which have been introduced from overseas, but such is not invariably the case. The great majority do belong, it is true, to this category; nevertheless, there are a few instances where the offenders are plants native to Australia. The case of *Ajuga australis* has been mentioned above; but a much better example is afforded by certain species of *Bassia*, a genus of plants allied to the Saltbushes and comprising a number of species of intricately branched shrubs with spinescent fruits, inhabiting the drier parts of the Commonwealth. The name "Bindy-eye" is

Bassia quinquecuspis, F.v.M., var. *villosa*, Benth.

applied in the North to those species in which the spines are rather long and penetrating, and so belongs to several *Bassias* in addition to the one forming the subject of these notes. Two very similar and closely related species, *Bassia Birchii*, F.v.M. and *Bassia quinquecuspis*, F.v.M., known to New South Wales farmers as "Galvanized Burr" and "Roly-poly" respectively, are listed as weeds in the Farmers' Handbook of New South Wales, and have been proclaimed noxious weeds in certain districts of that State. A hairy variety of the latter of these plants, *Bassia quinquecuspis*, var. *villosa*, Benth., is growing in great abundance at present along the fences and in some stock paddocks adjoining the Main North Road, near Parafield, whither it has evidently been brought by stock from the

North or from the Eastern States. The species belongs to the drier parts of Queensland, New South Wales, and Victoria, and probably also to the north-eastern and eastern parts of South Australia.

Description of Plant.—The plant is an intricately branched spreading shrub, from 1ft. to 3ft. high, more or less hairy all over. The leaves are alternate, almost flat, narrow, pointed at both ends, and from ½ in. to 1 in. long or sometimes longer. The flowers are solitary, each being attached by a broad oblique base to the stem in the angle made by a leaf. The flower is provided with from 4 to 6, usually 5, spreading spines, of which three are about ½ in. long, while the other two are shorter and almost united at the base. When the leaves fall the stems appear to be armed at intervals with groups of slender prickles due to the attached and spinescent fruits. The fruits subsequently become detached as burrs, each burr containing a single seed. The accompanying photograph will give some idea of the appearance of portion of a plant.

When dry the stems are very brittle, and the parts above ground easily break away. The spiny branches tend to cling together and the detached parts are rolled over and over by wind action, gathering up fragments of other and similar plants, so that compact balls are formed. These are driven along the ground and come to rest at fences and other obstructions, and it is along the fences that the plants are most numerous and conspicuous. Such behavior has given rise to the name "Roly-poly," which name, however, is usually applied in this State to the related *Salsola Kali*, a plant which behaves similarly in this respect.

Properties.—Owing to its tough and spiny character *Bassia quinquecuspis* is useless as fodder, for stock refuse to touch it. But the burrs readily adhere to wool or hair, so that stock spread the weed without checking the growth of individual plants. For these reasons it is obviously a matter of importance to get rid of this plant while it is possible to do so without great expense. This could be done by cutting and burning the existing plants and any young ones that subsequently appear.

(The writer's thanks are due to Mr. J. M. Black for confirming the identification.)

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on January 31st, there being present Messrs. A. M. Dawkins (Acting Chairman), P. J. Baily, J. B. Murdoch, F. Coleman, S. Shepherd, A. L. McEwin, Professor A. J. Perkins, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary).

Apologies were received from Messrs. A. J. Cooke, R. H. Martin, H. N. Wicks, and G. Jeffrey.

Change of Name of Branch.—Approval was given to the change of name from Kuitpo Industrial Colony to Kuitpo.

New Branches.—Approval was given to the formation of Branches at Hope Forest and Dingabledinga (Women's) and Yundi. In both instances the Board decided that those members resident in the Hope Forest and Yundi Settlements should be exempted from subscription to the *Journal of Agriculture* for two years. The following were enrolled as foundation members:—Hope Forest and Dingabledinga Women's—Mesdames A. T. Jeffris, F. Finchen, L. Osborne, H. Justin, M. Bates, F. Bowen, C. Nicol, C. H. Fisher, W. C. Catlin, E. Muldoon, G. Watson, C. Jackson, E. Peterson, H. Nielson, A. Searle, P. Willaston, C. Barclay, F. Eve, S. G. Coad, A. V. Lewis, Misses I. Barclay, E. Edmunds, M. and E. Searle, and M. Coad. Yundi—C. Sandstrom, A. F. Muirson, J. C. Normandale, T. J. Hart, C. Guthridge, A. Garvis, E. B. Gliddon, W. R. Hedger, B. Whittington, R. H. Smith, G. W. Sykes, J. V. McGinnis, G. Lomax, R. W. McAlister, W. C. Jones, J. O. Marshall, W. M. Field, and T. R. Smart.

Life Members.—The following members were approved as Life Members of the Agricultural Bureau:—Messrs. W. Manser (Mount Gambier), A. W. Magery and A. V. Mills (Berri), and W. Patching (Angaston).

New Members.—The following members were added to the rolls of existing Branches:—Clare Women's—Mrs. R. M. Hawker; Mundalla Women's—Mrs. H. Wiese; Mundalla—W. Miatke; Brinkley—Roy Forrest; Parilla Women's—Miss S. McCormack; Mypolonga—L. Rosser, N. Geuc, R. Llewellyn, A. Wedd, W. Vogt; Penwortham—S. L. Wayman; Belalie Women's—Mrs. W. J. Goodes; Barmera—A. J. West; Shoul Bay—G. Osterstock, A. J. Turner; Macclesfield—J. Schmidt; Belalie Women's—Miss M. McLeod, Mrs. M. Fife; Adelaide—George Bain; Parilla Women's—Mrs. C. Schumacher; Clarendon—Ron. Spencer, Max. Harper, John Langsford, Cecil and Verran Smart; Greenock—M. Schluter, M. Martin; Blyth—M. R. Williams; Kybolito Women's—Mrs. H. J. Williams; Black Rock—A. C. Smith; Wirrilla Women's—Miss C. Evans; Parilla Women's—Miss P. Foale, Miss P. Dauncey, Mrs. Carman; Blackwood—J. H. and D. H. Mellor; Inman Valley—S. Crittenden.

No. of members for approval, 37; present No. of Branches, 334; present No. of members, 8,050.

Several items were discussed in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on, February 1st, 1934:—

BUTTER.—Trade in butter throughout January fluctuated considerably, and owing to the extremely hot spells experienced the turnover lessened, but responded again when milder conditions set in. Whilst an improvement in local values was recorded during the month, the British market continued weak, and rates there touched new record low levels. This was very disheartening to producers and shippers, and was brought about through the Control Board's fixation of prices earlier in the season being above the price at which British traders were prepared to buy. At date the following local prices were ruling and London values for choicest Australian were then 63s. to 64s. per cwt. Choicest creamery fresh butter, in bulk, 1s. 1½d.; prints and delivery extra. (These prices are subject to the stabilisation levies.) Store and collectors', 4½d. to 5d. per lb. at store door, less usual selling charges.

EGGS.—The supplies of eggs kept up fairly well throughout the month, and with exporting having ceased, greater quantities were available for the local and interstate markets. Some limited shipments were made to Victoria and New South Wales, but

the bulk of the consignments were sold locally or placed into pulp for winter use. Values continued steady throughout. Ordinary country eggs, hen or duck, 3½d. per dozen; selected eggs, 1½ozs. and over, 6½d. to 7½d. per dozen.

CHEESE.—Production is now rapidly declining, as conditions in the South-East have been drier than for many years past, and this has had a serious effect on the flow of milk. There was no alteration made in these values and overseas exporting has now ceased. Local and Western Australian trade was maintained and stocks generally cleared from week to week. New makes, large and mediums, 5½d. to 6½d.; loaf, 6½d. to 6¾d.; semi-matured and matured, 9d. to 9½d. per lb.

BACON.—As usual during heat spells, bacon met with considerably reduced turnover. However, as an offset to this, cooked hams and bacon factory smallgoods met with increased turnover; but considerable stocks of bacon in process of curing are held by the factories. Rates were steady throughout the month. Best local sides, 9½d. to 9¾d.; best factory-cured middles, 10½d. to 11d.; large, 9d.; rolls, 8d. to 8½d. Hams, 1s. to 1s. 0½d. per lb.; cooked, 1s. 2d. to 1s. 2½d. per lb. Lard, prints, 6s. per dozen.

ALMONDS.—The quantities sent in to the open markets were not heavy, as most growers have ere this quitted the old season's stocks. However, the consignments which arrived met with steady sale, and buyers are now interesting themselves in the new season's crop. Softshells and Brandis, 8d. to 8½d.; hardshells, 4½d. to 5d.; kernels, 1s. 10½d. to 1s. 11d. per lb.

HONEY.—An improved demand for honey set in early in the new year, interstate buyers showing a little more interest in this commodity. The fact also of this season's "take" being likely to be a small one no doubt had an influence in this respect. Values continue without any alteration. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1d. to 2d. per lb.

BESWAX.—Supplies offering were not extensive, but there was no difficulty experienced in quitting lots as they arrived. Values continued on an even keel: 1s. 0½d. to 1s. 2d. per lb., according to sample.

LIVE POULTRY.—As usual at this season of the year, a large number of poultry farmers are quitting the old season's hens, and the majority of the birds submitted at recent sales have been only in poor to medium condition and of the lighter breeds. Whilst clearances were effected from day to day, the prices for the poorer sorts were easier, but for prime quality heavy-weight stock in all classes of poultry there was a maintained demand at satisfactory prices. We advise consigning. Crates loaned on application. Prime roosters, 3s. 9d. to 5s.; nice-conditioned cockerels, 3s. 2d. to 3s. 8d.; fair-conditioned cockerels, 2s. 6d. to 3s. 1d.; chickens lower; heavy-weight hens, 2s. 5d. to 3s.; medium hens, 1s. 7d. to 2s. 2d.; light-weight hens, 11d. to 1s. 3d.; couple of pens of weedy sorts lower; geese, 2s. 9d. to 3s. 9d.; goslings lower; prime young Muscovy drakes, 2s. 9d. to 3s. 9d.; young Muscovy ducks, 1s. 9d. to 2s. 6d.; ordinary ducks, 1s. to 1s. 9d.; ducklings lower; turkeys, good to prime condition, 10d. to 1s. 2d. per lb. live weight; turkeys, fair condition, 8d. to 9½d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons, 3d. to 4d. each.

POTATOES.—New season's, 6s. 3d. per cwt.

ONIONS.—New season's, 5s. 6d. per cwt.

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,
SHORT OR HEAD-HIGH. THE ENORMOUS POWER OF A

MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK.

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling and long trouble-free service.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

HANDLING A YOUNG HORSE.—The monthly meeting was held in the railway yards, where Mr. W. Pfizner gave a demonstration of handling a young horse, and prefaced his remarks by saying that a horse treated with kindness was made a servant for the rest of its life, but if treated roughly it might possibly develop into a horse that could never be trusted. The correct time to break in a horse was between the ages of two and four years. The horse, a two-year-old draught filly which was used for the demonstration, was caught, and Mr. W. B. Pfizner advanced very gently and quietly to the horse's head, when a halter was then put on. The next operation was to handle her legs, which was done with the assistance of a rope, one front foot being held up until the horse stopped straining, and immediately the horse stopped the foot was lowered to the ground. This was done so that the horse would allow its foot to be picked up without struggling or straining. All feet were treated in turn in the same manner. The moulthing was done with a bridle, so that the horse could see everything that was being done to it and not be frightened. It was not very long before Mr. Pfizner was able to make the filly answer to the rein and lead. (Secretary, C. Koch.)

KYBYBOLITE (Average annual rainfall, 22in.).

October 10th.—Attendance, 22.

HISTORY OF WHEAT IN AUSTRALIA.—Mr. L. Darcy read the following paper:—“Although Australia's first wheat crop was harvested as long ago as 1789, it was many years before the new settlements could rely on sufficient local production for local needs in all years. There were several reasons for the slow progress in wheat production during the early days of the different colonies. The main causes in New South Wales and Victoria were that the early colonists were pastoralists and not interested in agriculture. In South Australia the land boom—almost as soon as the province was founded—delayed the development of farming until land values had found their natural level. The States on the mainland were relying on the supply of wheat and flour imported from Tasmania, the first importation taking place in 1815, Tasmania thus being the first State to export wheat; and again in 1820 Tasmania made history by exporting the first wheat overseas, a shipload being sent to Brazil. The first wheat to be grown on the mainland was at Rosehill, New South Wales, in 1789, and the crop returned 200 bushels, which was set aside for seed purposes. Wheat-growing made very slow progress, and in the next 18 years the area under crop had only increased to some 6,000 odd acres. In 1806 the crops failed and wheat rose to £4 a ton. The selling rate was regulated by garrison order, and it became necessary to guard the wheatfields with armed sentinels. The high price of wheat during the famine years which followed—the shortage lasted until 1815—caused a great deal of activity in agriculture, and a far greater area was put under wheat. Victoria especially paid far greater attention to wheat growing, the earlier settlers—being mainly pastoralists—getting their wheat or flour from other States. South Australia has been an agricultural area throughout the whole of its history. The first crop grown in South Australia was at Hilton, 20 acres being sown in 1838. A crop failure in the

eastern States about this time, and wheat rising to 20s. a bushel, greatly assisted the early settlers of this State, and by 1841 the area sown had risen to about 4,000 acres. The discovery of copper in South Australia in 1843, and the Victorian gold rushes of 1850, caused a big increase in the population, which made a big demand for wheat and flour, which put South Australia on its feet as a great wheat-growing State. From £73,000 in 1851 the value of South Australian exports of wheat and flour to other States jumped to £212,000 in 1852 and £556,000 in 1856. The first export of wheat to Great Britain was made in 1845.

It seems strange that mining did so much to increase agriculture in the eastern States, while in Western Australia very little wheat-growing was done, and until mining started to decline, agriculture made very little progress, and as late as 1899 Western Australian exports of wheat only amounted to 1,600 bushels. It has made very rapid progress, however, and is now one of the leading wheat-growing States. The large-scale wheat farming of to-day owes its beginning chiefly to the passage in Sir John Robertson's Land Bill of 1861, which allowed Crown lands to be purchased on extended terms. The small farmer soon came into his own, and the wheat industry progressed very rapidly. By 1871 the Australian harvest totalled 11,000,000 bushels and rose to 21,000,000 in 1882-83.

Another factor in the development of the wheat industry was the use of phosphatic fertilisers which came rapidly into use between 1880-5 after many years of experiment in different parts of the Commonwealth. The construction of new railways, subdivision of large holdings, and the opening up of mallee country in South Australia and Victoria did much to increase the wheat production of the country. All over the Commonwealth wheatgrowers were suffering very heavy losses owing to rust and drought, and the present-day wheatgrower owes much to William Farrer, who after years of experimenting at his own expense produced a rust-resisting wheat, 'Federation,' which was put on the market in 1900. The value of this wheat can be judged, that in 1889 alone the loss by rust was estimated at £2,500,000.

The yield for the Commonwealth in 1900 was approximately 48,000,000 bushels, but by 1910 had almost doubled that amount, reaching 95,500,000 bushels, and the record harvest for Australia, 1930-1, which reached the total of 213,000,000 bushels. Last season Western Australia, Victoria, and New South Wales had about 3,500,000 acres each under wheat and South Australia just over 4,500,000 acres. At the present

THE MOST CERTAIN CHEAPEST, AND EASIEST

Method to Destroy

RABBITS

is with the

POISON CART

provided you use

GOOD
OLD

75, Grenfell Street, Adelaide.

time there are some 1,156 varieties of wheat listed in the Commonwealth, but the majority of them have never been heard of by the average wheatgrower, and only 272 of them are grown commercially.

In breeding they are a cosmopolitan lot. Some 20 different countries are represented in the breeding of some types of wheat in Australia.

The value of wheat as a source of income to Australia is very great, and last year's wheat harvest was valued at approximately £28,000,000, at an average of 2s. 3d. a bushel." (Secretary, A. Shepherd.)

WOLSELEY (Average annual rainfall, 18.52in.).

December 18th.—Present: 18 members.

ARE THE AGRICULTURAL BUREAUX WORTH WHILE?—Paper read by Mr. W. Butler:—"The above question must be answered yes. The Bureau has been established for 43 years, and from a small beginning has become a force to be reckoned with on account of the very large number of members, with Branches in nearly every place of any importance. In the early part of its career, the meetings were mostly held on a Saturday, when all the young folk wanted to be at the football match; but when they altered the time to 8 p.m. it was very soon seen that the young men were interested, and a far greater interest was manifest. Before the advent of the Bureau, matters were looking serious, and then scientists came to the rescue and showed the producers that the soil was in need of fertilizers, and the Agricultural College, by experiments, and the Bureau, through its meetings, enabled producers to obtain an increased yield in return for their outlay. By bare fallow well worked and a fair amount of super, it revolutionised cereal production. The crop competitions brought about improved conditions and increased yields per acre; they promoted a keenness to be the winner of the shield for the champion crop, and Parliament assisted the enterprise by subsidy, and the S.A. Farmers' Union have given the competitions a great lift with a splendid donation. Wonderful results have been obtained by top dressing and sowing different grass and clover seeds. Another grand feature in connection with the Bureau are the many Branches of the Women's Bureau, which are both very interesting and instructive to all; and we appreciate the splendid help that has been given by the Agricultural Instructors." (Secretary, A. Sharrad.)

APPILA (Average annual rainfall, 14.69in.).

October 6th.—Attendance, 12.

FENCING.—Mr. R. Harvie read the following paper:—"When erecting a fence, first procure well-seasoned split gum posts. I prefer either red or blue gum, although both have faults. Red gum is inclined to rot in the ground and the blue gum is subject to white ants. All posts should be of the same height, placed in a straight line, and at equal distances apart. A fence 3ft. 6in. is high enough to keep most livestock in bounds, but an extra 2in. is desirable for the boundary fences. The wires should be spaced as follows:—10in. between the barb and top plain wire; then 8in., 7in., 6in., and 5in. between each succeeding wire, with the bottom wire 6in. off the ground. If the bottom wire is too close to the ground silt and rubbish drifts underneath the fence; gradually the bottom wire becomes covered and soon rots. Strainers should be about 6ft. 6in. in length 3in. to 4in. above the ordinary posts to allow for the straining of the barb wire. Always try to obtain strainers without too straight a grain. Good struts play a very important part in the fence; they should be 9ft. to 10ft. long and kept fairly close to the top of the strainer. A good plan is to put in a post about 10ft. from the strainer and place the strut against the bottom of it. When boring the posts see that the holes are bored in the direction which the fence is running. This will obviate trouble when pulling in big wire through the holes. In stony country iron posts can be used with advantage. For division fences I favor

two droppers, in boundary fences one dropper to a post. T iron posts make the strongest job, but flat ones are more economical for a two-dropper fence; the wooden posts should be 27ft. apart. Make each strain about 15 chains long. The less strainers there are in a fence the fewer broken wires there will be. If notice is taken of a fence that has been up for a time, it will be observed that the wires when broken are rusted through at the strainer. There is no trouble in straining wires at this distance because one can tie the wires on the strainer and then strain from the middle. There is no trouble in getting the wires tight if the joints are securely fastened. The thick wire which has rusted seems to cause the most trouble. If a new piece of wire is joined in between the old it will not be so inclined to break. When tying the barb on top of the posts, use galvanized wire; it is not so likely to rust the barb as black wire. It is also unnecessary to twist the wire around the barb half a dozen times; one and a half rounds is quite sufficient." (Secretary, E. Wurst.)

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

FIELD DAY- AT BEETALOO VALLEY.

A tour of the Beetaloo district was made on the afternoon of October 30th by members of this Branch, accompanied by Messrs. E. L. Orchard and J. B. Harris (District Instructors). Messrs. J. Halse's and P. Curtin's orchards were first inspected, where grey scale was found to be very prevalent. The party then visited Mr. P. Curtin's farm. A crop of wheat, Sword variety, which was one of the best in the district, was expected to reap 10 bags or cut 3 tons to the acre. Messrs. Ryan Bros.' orchard was then inspected. It was in excellent condition. Stone fruit, apples and oranges were "setting" well. Mr. Ryan's glass-house tomatoes showed indications of bearing a prolific crop. The next places called on were Mr. J. Arthur's and Mr. B. Giddings's orchards. Mr. Arthur had a very good crop of oranges, and his two-year-old orange trees (about 200) were doing remarkably well. Mr. B. Giddings's oranges were looking well; the crop was light, but next year's showing was very promising. Apples, pears, and a crop of potatoes came in for very favorable comments. His hay crop was also a splendid cut, consisting of Waratah wheat and Early Burt oats. In the evening Mr. Harris addressed a well-attended meeting, and spoke on the "Control of Garden Pests and Diseases."

BLACK SPRINGS.

October 6th.—Attendance, 16.

FARM SIDE LINES.—Mr. N. Heinrich read the following paper:—"A farm is not complete unless it has a certain number of main side lines, such as sheep, pigs, cows, poultry, &c. At the present prices a farmer cannot make wheat-growing pay. In order to regain his position side lines are the only help, unless he deals in horses or sheep, but the success of this activity is by no means certain. About six to eight cows would be sufficient to keep the home. I prefer Jerseys or Shorthorns; the former produces the richest cream but does not give quite the amount of milk as the other breed. If it is decided to keep poultry, both White Leghorn and Black Orpington are good layers. The rearing of pigs would be another avenue of revenue. Suckers can be bought for very reasonable prices, and this pays better than breeding. Crushed wheat, oats, or barley and bran are suitable feeds for pigs. On a 1,000 acre farm about 300 sheep could be run on an average throughout the year, breeding lambs or keeping a flock for shearing, and disposing of the surplus in a suitable market."

Mr. R. Heinrich read a paper, "Farm Pests," and Mr. J. Howard gave an address on "Bulk Handling." (Secretary, K. Dunn.)

THE DRYING OF FRUIT.—Paper read by C. F. Wilksch:—"Fruit drying is a very old industry. In history books we read of the ancient Greeks, Turks, and Egyptians drying figs and dates; but however old the industry, a person can never use too much care in the cleanliness and soundness of his fruit. A gardener must ask himself, 'Is it as clean, sound, and appetising a product as is possible to produce.' He must remember that fruit which does not taste fresh and sweet in its natural state cannot possibly be a first-class article; in fact, it should not be dried for human consumption at all. Cleanliness is an important factor. See that the trays are clean and free from dust. All fruit should be dried off the ground on wire trellises to escape all dust caused by walking among the trays. Another advantage of this is that in stacking no dirt or dust adheres to the bottom of the tray, which would be shaken on to the fruit on the tray beneath. It also eliminates a lot of stooping, and this enables the operation of stacking or spreading to be completed easier and quicker. On no account allow the fruit on the trays to get wet or damp; it will make it darker and spoil the appearance. Care should be taken in taking the dried fruit off the trays. The fruit should not be hard and brittle, but soft and pliable. When taking off fruit, any discolored, dirty, or blemished fruit should be discarded, to facilitate grading and packing operations. *Apricots.*—The fruit should be quite ripe, but firm, to stand handling and keep a perfect shape. Cut and remove stone and stem, placing the fruit level on to the tray to hold the juice and prevent sticking when dry. Sulphur as soon as possible. Never allow apricots to stand all day before sulphuring. From 5 to 6 hours in a good even sulphuring should be sufficient. A day or two in the sun should dry off the juice, after which, if stacked, the fruit should be a good color. The ideal for apricots would be to pick, cut, and sulphur the same day; but if a grower who has anything like a big garden did this, the apricots would soon get ahead of him, and he would lose a lot of fruit. *Peaches and Nectarines.*—The same treatment as apricots, with perhaps a little more sulphur. Windfalls may be used if they fall on soft soil and are not bruised. If parts show black and are bitter, they should not be used. Clean the windfalls thoroughly with a brush or water squirted on them with good pressure. Peaches can be peeled either after sulphuring or after dipping into boiling water. They are very nice done that way, but it is not a paying proposition. Last year the A.D.F.A. only offered 1d. lb. more for them than the unpeeled, and taking into consideration the loss of time and weight, it does not pay. *Prunes.*—Ripe, but firm; not over-ripe, as then they lose weight. Dip as soon as possible in a solution of boiling water and caustic soda, approximately $\frac{1}{2}$ lb. soda to 10 gallons of water. Some varieties need more or less, but this can be told by trying a few. The dipping cracks the skin, causing the prune to dry more quickly, and prevents bloating or boiling. Dry in the stacks after a few days of sun, to improve the color and texture. When about half dry, loosen or stir them on the trays; this will prevent sticking and mould forming on the underside, and result in a more even drying. When dry, to shine up, dip in hot or boiling water and a little wattle gum and glycerine. *Plums.*—The same treatment as prunes, but in the case of light plums 6 or more hours of sulphur must follow immediately after dipping. If in drying plums such as Golden Drop, the skin of the dipped fruit should dry before sulphuring, a light sprinkling of water is very beneficial. *Pears.*—Pears are the hardest of all fruits to dry, to get them to a pale-yellow color is a difficult thing. Very often they turn a brownish or a pinkish tinge. Pick when fully developed but still green in color. If left on the tree until yellow, the centres usually turn black. After picking, store to ripen. For quick and even ripening, paper line the cases. When cutting be sure to remove all the stem, blossom, and core, as the cores show up white when dry, and spoil the appearance of the pear. Sulphur as soon as possible for about 8 to 10 hours, or longer, until they are that soft that it is hardly possible to pick them up intact. Spread the trays in the sun for a few days, then stack. If dried in the sun altogether, they turn dark and crinkled. Should dull and rainy weather set in, watch for vinegar, flies, or mould on the freshly-cut pears, and at any signs of either, a slight dose of sulphur will remedy the defect. Do not allow them to get too dry nor take them off too soft, but a nice pliable condition without being shifty. *Apples.*—It does not pay to dry apples, but if there is no market for them, it is better than letting them rot or feeding them to the pigs. Peel and core the apple and slice into rings. On no account use a salt solution, but meta-bi-sulphate, a crystal which turns the apple a very nice color. Place singly on galvanized-wire trays if available. If not, wooden trays will do, but they must be clean, as apples, being white, show any signs of dirt. The disadvantages of wooden trays are slower drying and the apples are apt to stick to the wood. If at all possible, apples are better for being dried the same day as cut. *Currants.*—Be sure the currants are ripe. If not, the fruit will be reddish instead of black, and

will not have such a good flavor and texture as the ripe fruit. Dry in the shade on racks. If no racks are available, spread on trays, but have the trays well blocked to allow plenty of ventilation. If spread on trays an occasional spreading in the sun will help to dry quicker without hurting the fruit. When dry enough to rub off the stems, pass through a buck currant riddle, to remove coarse stems and bucks, and they will then be ready for the packing shed. Any farmer or townsman who has some fruit trees on his property and has more fruit than he can use fresh, should try his hand at drying the surplus. A few trays can be purchased from a carpenter or made out of packing cases. These, if taken care of, would last for many years. The sulphur box will not be a great expense. A framework of wood covered by bagging, with a few coats of whitewash, will fill the bill. This with an occasional whitewashing or a replacing of bagging will also last for years. Any amateur who does not quite understand the treating of some varieties could get any advice from the nearest fruitgrower." (Secretary, A. Schubert.)

BULK HANDLING OF WHEAT.—The meeting took the form of an inter-Branch visit, and the following paper was read by Mr. T. Rodda:—"This subject is of vital importance to farmers. The difference between production cost and the selling price is the farmer's profit. We are unable to raise the price of wheat; therefore we must seek to lower the cost of production if we are going to be successful wheatgrowers at the present time. There has been a great advance during the last 30 years in our methods of cultivation. However, the marketing and handling of produce is hopelessly out of date. Bulk handling is a step in the right direction to improving our marketing and handling. In the first place, it will raise our standard of wheat. Under the present system all kinds of wheat go in the same stack, *i.e.*, smutty wheat, wheat with too much barley in it, and in the new country, mallee leaves. If any wheat be docked, it is all stacked with f.a.q. wheat, and must have a tendency, when shipped to other countries, to lower our standard in that particular country. A reduced price is obtained than would have been the case had it gone through the bulk system, when all docked wheat would be stacked separately, and would be marketed separately, or used for home consumption. Second, there would be less damage from weather, mice, and rats. A great quantity of new cornsacks is required for rebagging, and so much extra work that could be done away with under bulk handling; mice and rats can do very little damage to wheat stacked in bulk. Third, less handling costs. The Western Australian scheme has shown how costs can be reduced. I have included the report of the Royal Commission that investigated the costs of the scheme, which was attacked by grain merchants, those interested in cornsacks, and others handling the farmer's wheat; but the figures incontestably proved that the pool could save the farmers 3d. a bushel each year through handling wheat in bulk. Handling costs could be greatly reduced here as well as in Western Australia. Fourth, a saving in freight and loading. There have been shipments of bulk wheat sent from Port Adelaide which have proved a saving in freight and loading. In New South Wales a vessel commenced loading at 8 a.m. and at 10 p.m. it was completely loaded with 7,500 tons. The same vessel when loaded with bagged wheat on a previous trip required 16 days. Fifth, a saving of cornsacks. We have sent £1,000,000 out of this State during the last 2 years for cornsacks, and over £5,000,000 from the Commonwealth. One of the biggest objections which might be raised against bulk handling is that of unemployment. Mr. J. G. Boyle, president of the Wheat Growers' Union of Western Australia, said that although his organisation had at first viewed the scheme with a very critical eye, it had come to the conclusion that it was one of the finest for the reduction of costs. The cornsack bill of Western Australia was over £2,000,000 a year, while exchange amounted to over £500,000. If this amount is kept in Australia, it would more than compensate the men who would be thrown out of employment. It may be said that the scheme would be too costly; but a scheme that will pay for itself in 10 years, and save between 2d. and 3d. a bushel to the wheat grower, is one which growers ought to study and discuss." (Secretary, T. Howlett.)

CARE OF FARM IMPLEMENTS.—Paper read by Mr. H. Reschke:—"To work a farm of average size, exclusive of power, the plant costs between £500 and £750, whether motor or horses are favored. Unfortunately this price is not realised when selling the plant, and so it depreciates in value. The scrap value is very low in comparison with the initial cost and so this value must be allowed for yearly, to have some money laid aside to purchase further machinery when necessary. Often the depreciation of machinery is as high as 20 per cent., and thus it becomes a heavy charge upon production costs, and it must be taken into consideration as its depreciation is brought about by wear and tear in gaining a profit. This very high rate of depreciation is usually due to careless use of implements, and it must be admitted that a method by which production costs can be lowered is to bestow a greater amount of care upon tools and implements. One of the chief ways by which this can be done is by housing. It is very frequently seen where a harvesting machine costing, say, £250, is left in full exposure to the weather from the completion of one harvest to the commencement of the next, or the inadequate shelter of a tree is given, but it must be apparent to any casual observer that if the machines were housed, well oiled to prevent rust, and kept in a better state of repair, they would be more efficient and last longer. To save £50 in depreciation means a saving of 3d. a bushel for 4,000 bush. of wheat—quite a consideration when the amount of money obtained for wheat is a question of vital importance.

Many experts have said that the actual average lives of binders and harvesters are one-half of what they should be. Why is this? Exposure to weather for 10½ to 11 months does more damage in adding to the depreciation than the actual wear and tear for one to one and a half months. The care of farm machinery thus readily divides itself into three heads:—(1) housing or protection from weather; (2) repairing; (3) painting.

1. *Housing.*—The necessary equipment needed to operate a farm should be regarded as capital invested in a business and made to earn as large a profit as possible. If this equipment is exposed to the weather it is not likely to do good work for more than a very few years, but if adequately protected should last for more than double the time. This means a great reduction in depreciation and a factor we must consider, as it can definitely be seen what a great saving will result by properly housing implements. The objections of many people may be aroused by the cost, but an expensive shed is not necessary, and by utilising the rough timbers available in many districts a serviceable shelter could be constructed for £50. If a man is careless his depreciation may be 20 per cent.; if careful, say 8½ per cent. This means that if the cost of plant is £750, the depreciation at 20 per cent. is £150 per annum, whereas if 8½ per cent. it is only £62 10s. This saving, that is £97 10s., is brought about by housing, so the shed is more than paid for in one year by its saving of depreciation.

2. *Repairs.*—It is impossible for a machine to render efficient service when in a bad state of repair or badly adjusted, for it means that the wear and tear is increased considerably and depreciation increased. Thus it is advisable to keep all wearing parts properly adjusted and repaired. These repairs should be made systematically, and at times when there is no urgent work requiring attention. Urgent repairs—breakages made when machines are actually working—should be executed immediately. It is no good using binder twine and fencing wire, or inefficient working will be the result. A careful operator will note, while using the machine, repairs which are necessary when the season's work is completed and keeping a record of these attached to the machine on cardboard, or something of that type, will know definitely what jobs are to be performed to put the machine in good order for immediate work. This overhauling is conveniently done in winter when it is too wet for outdoor work. Duplicate parts should be ordered early and repairs which cannot be performed in the workshop completed as soon as possible. If left to a later period near the time one intends repairing the plant, it is found the parts are missing, and so much valuable time is lost. Thoroughly clean all machines when overhauling, for in this way many defects are noticed which normally would be overlooked. Wearing parts will be detected, and if it is impossible to take up this wear, new parts should be ordered and put in. This not only reduces depreciation, but also may be the means of avoiding a breakdown during the busy season, when a few days delay may prove to be very expensive.

3. *Painting.*—Unless a house is painted it does not present a finished appearance. The same applies to vehicles or implements. A greater point, however, than its appearance is that paint is an excellent preservative. It resists the decaying influences

of air and moisture on woodwork and protects metals from rust. It is often true that working parts of a machine suffer more from rust than wear. Thus it is essential to keep wearing parts well oiled as well as looking after the painting of other parts. Generally farmers can mix their own paints cheaper and more satisfactory, using red lead as a base for rough jobs and white lead with suitable colors for finer work. A coat of hot tar is a very effective preservative and is particularly good for naves and felloes of wooden wheels. A thin coat of boiled oil gives an excellent protection to metal surfaces, preventing rust, and also renews old woodwork where the paint has faded, but not lost its color or body. When applying new paint it must be remembered that the surface must be dry and thoroughly clean. Upon new or very dry wood the first coat should be one of raw linseed oil only. The cost of painting material is very small, but its value in prolonging the life of farm implements is considerable.' (Secretary, C. Whillas.)

ROBERTS AND VERRAN.

November 1st.—Attendance, 23.

THE LOCAL AGRICULTURAL BUREAU.—The meeting took the form of an inter-Bureau visit. Mr. T. Winters (Secretary of the Taragoro Branch) read the following paper:—“This subject is one which should bring forth in the general discussion many suggestions for the benefit of Branches, which should retain, at least, if not stimulate, interest of all members. The Bureau can only prove helpful to farmers if our interest is keen. The two Branches met here to-night on this our first inter-Branch visit are only small units of a State-wide organisation. The success of our Branches lies entirely in the hands of its members. The writing of papers appears to be a drawback. The choice of subjects to go on the syllabus can be improved if the members come prepared—at a meeting previously arranged—to do so. The choice of subjects is better left to the writer who is responsible for the paper, for he will suggest for the syllabus and select a subject with which he is conversant. Farming provides so many and varied subjects to suit all members that drawing up a syllabus or writing a paper should not provide such a drawback. The papers and discussions provide much benefit to other members, for very few of us hold the same ideas or opinions, and thus the expressing of them opens fresh views for other members. The Bureau, by

the medium of papers and discussions, assists us to express our views, &c. The discussion enables us to speak and understand how to address the Chairman, &c. By this means alone it assists all members to overcome any fears or shyness in public speaking. The discussion is an education in expressing our views concisely. The local Bureaux provide a very helpful education to farmers. Another fact is that we are enabled to enjoy lectures and read bulletins by officers of the Department of Agriculture on many different subjects dealing with primary production. The election of officers is another outlet for fresh talent. Officers should be changed more often, for by so doing interest may be better maintained, and it gives everyone a chance of taking a fresh responsibility in the affairs of the Branch. Because an officer has held a position for three years that is no reason why another member should not be put in office. The Secretary is the most important officer and on that account he should be relieved by some other member capable of doing the job. The same change should be effected in the other officers. The Branch would possibly be much improved by this change. Another point is the selection of delegates for the Annual Congress held each year. The member who has been most regular at meetings should have first chance. As he is interested enough to attend his own Branch, he will certainly carry his interest to Congress and be able to give a comprehensive report on his return." Discussing the paper Mr. O. Guy thought some members often failed to be of assistance to their Branches because they would not listen to other views and did not take part in the subject open for discussion. Mr. E. Polke said meetings of this kind should stimulate interest in the Bureau. He asked members to give a little serious thought of the benefits obtained by association with the Bureau. Mr. J. Crooks considered inter-Branch meetings should stimulate interest in the future. Members who wrote papers should be allowed to choose their own subject, because they could write about something with which they were conversant. When a member consented to write a paper he should not allow other meetings to interfere, but fulfil his duty to the Branch. He should always give of his best by giving plenty of time to write and also study other subjects by being prepared. This always meant a better discussion. Agricultural officers could be invited to attend meetings and so help to make the Branch more lively. Mr. S. Barber thought changing of officers was not for the best interest of the Branch. If fortunate enough to have good officers, why not keep them as long as possible? New subjects should be introduced which would materially increase the information. There was too much repetition of subjects. Mr. Crabb disagreed with the writer regarding his ideas of choosing members for Congress. If this idea was put in practice the most regular attendant may not be a man suitable to go. He considered anyone who was acting should realise his duty to the Branch and make determined efforts to gain as much knowledge for that Branch. Mr. J. Pahl did not advocate the changing of officers; it was difficult to get suitable men to carry out the job successfully, especially the Secretaryship. Mr. M. Guy said such meetings would greatly benefit both Branches and create more interest. Mr. C. Masters agreed with the writer as regards changing officers. He favored the Vice-President becoming Chairman next year. He would understand it was his turn and would naturally try and fill the position to the best of his ability. Drawing up a syllabus should not be very difficult if every member came prepared with suggestions instead of the Secretary giving suggestions and others adopting what he said. The Bureau itself was an education by which they could benefit. Lectures by agricultural officers were frequently given free of charge, also useful information on all subjects was printed in the *Agricultural Journal*, which at 2s. 6d. was the cheapest paper farmers had printed for their use. Mr. E. James said the Bureau was an essential and all farmers should become members and keep the Branch active. Mr. R. Jonas believed punctuality was essential. Members would be well advised to give this more consideration, which would help to run a Branch more successfully. Mr. H. Smith said members should always endeavor to attend and do something to help maintain interest in the Branch. More interest was taken when experts were invited; why not always attend other meetings and make them interesting? (Secretary, C. Masters.)

OBJECTS OF CULTIVATION.—Paper read by Mr. W. Giles:—"Good cultivation is necessary to get the best results out of the land. In early times the operations of ploughing and harrowing were usually badly performed, partly owing to the lack of proper implements and often through carelessness. In 1733 an English farmer, Jethro Tull, called attention to the large crops which he obtained by thorough cultivation. Tull even claimed that good cultivation was of itself sufficient to maintain the fertility of the soil and that where it was practised the need for manures would never arise. In 1933 the reports of the agricultural experts on the crop growths and conditions in all districts of our State was the same, namely, that the crops on well-worked fallow were standing up to the adverse conditions admirably, whereas those on stubble and poorly worked land went off. *Ploughing*—This is usually the first step in cultivation. The object is to loosen the soil and then invert it, thus exposing a fresh surface to sun and air. In the result the soil is left loose, so that water and air can enter freely. Ploughing also affords a means of burying weeds, crop residues, and farm-yard manure under the surface, so that they are converted into humus at the place where they do the most good. The proper depth to plough depends upon circumstances and the depth may vary from 3in. to 7in. Generally it is inadvisable to go deeper than the surface soil, which can be distinguished by its darker color from the subsoil, which is poor in organic matter and has been imperfectly weathered. By bringing up large quantities of subsoil to the surface, a soil may be injured for years. Soils with a loose, sandy bottom do not necessarily require such deep ploughing as stiff clay, which it may be necessary to loosen to permit free passage of air. When ploughing is done early in winter, the operation can be performed deeper, because winter rains will wash down the finer particles, forming a fairly dense seed bed, through which the water will rise to the crop during dry weather. If ploughing is done late, then such deep working is not advisable because the soil is left so loose that plants growing on the surface may receive little water from below. Late ploughing should usually be shallow. The best results in ploughing depend upon a suitable

The SCIENTIFIC WET AND DRY PICKLE

wetness of soil; this applies more particularly to heavy lands. If too wet, clay land will be more or less puddled, the crumbly nature being broken down, and the ground may dry in hard lumps. There is less injury caused by ploughing too wet in early spring than there is in spring, because the frequent wetting and partial drying in winter tends to break down the lumps and reproduces that crumbly nature so desirable in heavy soils. There are also drawbacks to ploughing land too dry. The land is less effectively pulverised by the plough and, moreover, horse labor is very greatly increased. Cultivators are used for scarifying the surface and preparing a loose mulch on fallows during spring and summer, and for loosening up the surface previous to seeding. For these purposes a depth of 2in. to 3in. is sufficient. Where the ground has set hard, a spring-tooth cultivator can be used with advantage, because it leaves rather a coarse mulch, which is more effective than a fine one. In all cultivator work it is a mistake to go too deep because it is desirable to retain a firm seed bed at the depth at which the seed will be planted. Harrows are used to form a mulch where the surface is already fairly loose. They are relatively light of draught and a large area can be covered in a day. Also ploughed ground is usually broken down by harrows. Light harrows are also used for covering the seed and sometimes for killing weeds which have just germinated and before they have much grip of the ground. In districts where red land occurs, if rain falls after the drilling operation is completed, it is often necessary to harrow the land in order to break the soil crust which becomes too hard for the young wheat plant to break. Rolling is sometimes done in order to break clods and thus prepare a tilth in preparation for seeding. Rolling is also sometimes desirable, either before or after drilling a crop, in order to compact the soil and enable it better to draw up moisture from below. In order to reduce moisture by evaporation, a light harrow sometimes follows the roller to create a light surface mulch—a hard rolled surface being particularly favorable to loss of water by evaporation.” (Secretary, C. Altmann.)

SOUTH AND HILLS DISTRICT.

HOPE FOREST.

GENERAL FARMING.—Mr. Muller, of Myponga, read the following paper:—“As in all other newly settled areas in the southern districts of the State, the first thing that requires attention is the sweetening of the soil, and the quickest method to do this is to plough the land and leave it for no less than 12 months. A slower way is to plant it with Subterranean clover. Never try and do too much; it is better to prepare a small acreage and do it well, because the land must be planted with the first rains to ensure the germination of the seed. A point that must not be lost sight of is to never overstock. Always give the pastures adequate fertilizer—about 2cwt. to the acre is recommended. It will improve the land, feed, and the stock. The outbuildings, such as cowsheds, horse stables, pig sties, &c., should always face the east, and be on high and dry land. See that they are free from draughts, with dry floorings, built high and wide, so that they will be cool and provide plenty of room. For perennial pastures, I suggest and have had the best returns from Subterranean clover, rye grass, *Phalaris tuberosa*; for annual crops, Cape barley and Algerian oats; and Planters’ Friend for the autumn.” (Secretary, A. Eve.)

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

November 30th.—Attendance, 9.

IMPROVING FLOCKS.—Mr. M. Rowsell read the following paper:—“It is an accepted principle in sheep breeding that improvement begins when the flock-owner decides to use pure-bred rams of the breed found to be the most suitable for his district. If all owners of small flocks followed this rule instead of using rams—the breeding of which they know little or nothing—they would soon have sheep showing a similar type, quality, and grade of wool. Well-bred sheep eat no more and often less than nondescripts, and on that score alone they must be more profitable. To obtain best results, ewes must be carefully culled, and there is no better time to do this work than at shearing or just before. Then the animals that are bad ‘doers,’ carry faulty fleeces, are weak in constitution, can easily be detected and a cull mark put on them. Particular care should be taken to see that the ewes have sound, good udders and perfect teats. In shearing, many lambs have their teats injured, and later cannot suckle a lamb properly. The cull ewes should be

fattened and sold for slaughter. By regular culling and disposing of all the objectionable ewes and keeping all the best ewe lambs instead of selling them, the flock will steadily improve on the soundest lines. To get the best results from such ewes, rams should always be typical of the favored breed. In buying rams it is advisable to purchase direct from the breeders 'in the wool.' This in itself is a guarantee regarding their breeding and the class of stock they are likely to throw. Buyers of shorn rams at country sales often pay higher prices than they would have paid for better sheep in the wool direct from the breeder earlier in the season. Wool, shape, and constitution are the three necessary points the buyer of rams has to consider, and those who neglect to buy early cannot expect to get rams of the best type, seeing that the pick are always sold first. Many people have the wrong idea that any sort of ram will do. Every breed has its special qualities, and each does well when kept under conditions suitable for its proper development." Mr. Lines, of C.S. and I.R., spoke on "Coast Disease." (Secretary, J. Wood.)

RABBIT DESTRUCTION.—Mr. D. Learmonth read the following paper:—"The law in regard to rabbit destruction is worthy of more serious consideration than it generally receives. One District Council does its job and sees to the destruction of the pest, another Council does not seriously tackle the work and, in consequence, their district proves to be a breeding ground for the rodents. There are landholders in all districts who consistently kill their rabbits, and their efforts are nullified because their neighbors do not take any action. There is only one way to overcome this pest, every landholder to tackle the job in a determined way and all working at the same time. There is no doubt about the necessity for killing the rabbit. A grazier told me recently that he had killed 9,000 rabbits since December, 1932, and he estimated that five rabbits ate as much as 1 sheep. If that is correct, it means that if these 9,000 rabbits were left alive they would have consumed the feed which would have kept 1,800 sheep. Again, to have left those 9,000 rabbits for 1 year would have increased the number at a low estimate by 100,000. The revenue to Australia for export rabbits and skins is sometimes referred to. Nearly 108,000 carcasses were shipped recently, in one shipment. Put these down at an average net return to Australia of 6d. each, which equals £2,700. Again, take five rabbits to a sheep and in place of those 108,000 rabbits, an extra 21,600 sheep could have been kept. Put the wool from those sheep down at ten pounds per head at 1s. a pound and £10,800 is the result, thus showing a dead loss to Australia of £8,100. There still remains the carcasses of the sheep, which if, valued at 10s. off shears, gives £10,800, making a profit in favor of sheep as against one shipment of rabbits £18,900. The Australian landholder gets no return from the production of rabbits. He loses his grass, his crop, and usually has to pay to have the rabbits destroyed. What is the best way then, to get rid of rabbits. This depends on the class of country. Level country without many rocks should be fairly easily cleared. Dig out all warrens. If this has not been done for some years it will fairly expensive, but to get rid of rabbits their homes must be destroyed. If possible, have dogs and hunt up any rabbits that are out, then close up all entrances except that one where digging is commenced. If possible put the top spadeful aside and when the warren is finished, or next day, put the earth back in the warren with the grass on top." Discussing the paper, members thought the warren should be left open for several days. In rough ground with big rocks, the rabbits' home was much harder to destroy. Wire-netting could be used with advantage members thought and stones broken up to the size of road metal and the holes filled in. In sandy ground the entrances should be dug well back and the holes fumigated. Other suggestions were for the Government to pay a bonus on rabbit skins to make them a payable price say an average of 1s. 6d. a pound, it would soon be returned in extra wool and meat, or subsidise the rabbit killing, as was already done by the Government in placing boys with farmers. Mr. Vigar of Mount Hope Branch said that they could not get along on the Peninsula without the poison cart in summer and traps when the crop was beginning to grow. All agreed that every landowner must co-operate if much good was to be done in the way of rabbit destruction. (Secretary, D. Smith.)

MILANG (Average annual rainfall, 14.97in.).

DAIRY HERD IMPROVEMENT.—Paper read by Mr. C. Lund, Strathalbyn:—"In dealing with this subject, the five following points are of utmost importance:—(1) Breeding. (2) Feeding. (3) Testing. (4) Culling. (5) Pasture management. (1) *Breeding.*—The first consideration in breeding is to secure a good sire. Breed from the best producers and set a standard in the herd and try and breed from cows that are above that mark. Keep the bull in good health and condition. Line breeding is better than in-breeding. Line breeding means that the blood of the sire in use is not lost after the first 3 years when ordinarily the bull would be on his daughters. Keep the herd up to breed characteristics and at all times remember that the better the sire the better the future herd. (2) *Feeding.*—A cow cannot do justice if she is not fed to her liking. Feed for production, but always remember that over-feeding of concentrates is not payable if carried to extremes. It is better to put it in the bucket than on the cow's back, but do not stint the cow when she needs it. Always watch the cow and feed her accordingly." The speaker also dealt with ensilage, chaff, and natural pastures and recommended linseed, crushed oats, bran and pollard. (3) *Testing.*—This is perhaps one of the most important factors in dairying, for without the true record of each cow it is not possible to say which cows are profitable. Weigh the milk each day and enter the results on a chart. Endeavor to join an association

or, if this is not available, do the testing on the farm. (4) *Culling*.—After testing, culling can be carried out. An excellent idea is to set a standard, say 200lbs. butter-fat, and cull out all cows which are not doing this and so gradually raise the standard of the herd. (5) *Pasture Management*.—Have the pastures so arranged that the herd will come on to fresh feed each week. This can only be done by having small paddocks, so that when one is almost eaten out the herd can be moved on, and followed with dry stock to clean up the pastures. The young growth is always the sweetest and best, try and have the cows coming in a rotation of 1-6 weeks. Prepare the pasture by top-dressing, harrowing the ground at early stages of the season, and planting grasses where rainfall permits." Mr. Lund then discussed at length how the Dookie Agricultural College Ayrshire herd in Victoria (of which he was manager for a considerable time) was raised from 215lbs. butter-fat to 507lbs. This was done by culling, feeding, and testing. (Secretary, L. Yelland.)

THE FOOD VALUE OF MILK.

The following is the first of a series of extracts, taken from Bulletin No. 340, issued by the Connecticut, U.S.A., Agricultural Experimental Station. Other extracts will appear in subsequent issues of the Journal.

Milk has been used as a food for man for many centuries, because practical experience taught that it was an extremely valuable adjunct to the human dietary. A sound scientific explanation for this age-old custom has been obtained in recent years, and we now understand why races accustomed to the use of liberal quantities of milk are unusually sturdy. Designed by nature to meet the requirements of the rapidly growing new-born, milk also finds a place in the dietary of the adult; more than any other single food, it meets the needs of the human body.

At what time man began to use the milk of domesticated animals may never be known, but this certainly occurred at a very early stage of civilisation. The place of origin of our domesticated cattle is not known with certainty, but they appear to be closely related to the wild aurochs or urus of Europe, Western Asia, and Northern Egypt. It is probable that the original domestication did not occur in Western Europe, but that the ox was brought from Asia by neolithic man in his migrations. Records found in tombs, caves, and camp sites indicate that the Aryans of Asia were among the earliest herdsmen; that the Swiss lake dwellers had domesticated the cow; and that the Egyptians kept cattle as early as 3500 B.C. References to milk or milk products in the Bible are so incidental as to indicate its common use from prehistoric times.

Although the cow is probably the most widely used source of milk for human food, many other species are likewise employed by man. Goats supply milk for the Arabs, South Europeans, Latin Americans, and the Spaniards. The camel supplies the Egyptians and the Arabs; the mare, the Tartars and the Mongols; and the reindeer, the Lapps and Eskimos. The inhabitants of Asia, especially those of India, milk the zebu, or Indian cow; and the Chinese and the Filipinos use the water buffalo. Sheep are milked in the Netherlands, in Greece, in Czecho-slovakia, in Italy, and in the Balkan States. The yak, belonging to the bison family, supplies the natives of Mongolia and Tibet, and milk from the llama, a relative of the camel, is used extensively in South America. However, in many countries even these substitutes for the cow are lacking. Under such conditions the tendency is to prolong the period of normal nursing, sometimes to an extraordinary extent; thus the mothers in some Indian tribes, among the Eskimos, and the poorer Chinese and Japanese nurse their children four to six years, or even longer.

In recent years evidence has accumulated rapidly to show that milk contains substances indispensable to life.

THE COMPOSITION OF MILK.

Milk is a fluid elaborated and secreted by the mammary glands from nutrients brought by the blood stream to the gland cells. It contains a mixture of several proteins, a carbohydrate, fats, inorganic salts*, vitamins, and water in such proportions and combinations that it makes an ideal food for the young of the species. The milk sugar, lactose, and the chief milk protein, casein, are found nowhere else in the vegetable or animal kingdom.

Although all milks contain similar, or at least closely analogous, chemical substances, each species of animal produces a milk peculiar to itself. The species characteristic is largely a matter of the relative proportions in which the different

*The inorganic salts contained in milk comprise what is left when a sample of milk is evaporated and the residue is heated until all combustible components have been burned away. The residue is also frequently referred to as the ash, or sometimes as the mineral salts of the milk.

components occur, as is shown in Table I. From these data it will be readily appreciated that the food value or the composition of milk must be discussed in terms of the species from which the milk is obtained.

TABLE I.—*The Average Percentage Composition of Different Milks Used by Man.*

Species.	Water.	Casein.	Albumin.	Fat.	Lactose.	Ash.
Man	87.41	0.91	1.23	3.76	6.29	0.31
Cow	87.27	2.95	0.52	3.66	4.91	0.69
Goat	84.14	3.04	0.99	6.00	5.02	0.81
Sheep	81.90	4.57	1.26	6.52	4.82	0.93
Buffalo	82.14	4.29	0.49	7.44	4.81	0.83
Camel	87.04	3.49	0.40	2.76	5.57	0.74
Horse	90.68	1.27	0.75	1.17	5.77	0.36
Ass	89.88	0.73	1.31	1.50	6.09	0.49
Reindeer	68.2	8.4	2.00	17.1	2.08	1.5

Table II., compiled in Germany in 1899, indicates an interesting and plausible relationship between the protein and the inorganic salts content of the milk and the time required for the new-born of different species to double their weight at birth.

TABLE II.—*The Composition of Milk in Relation to the Growth of the New-Born.*

Species.	Period in which Weight of New-Born is Doubled.		Salts.	100 Parts Milk Contain--	
	Days.	Protein.		Lime.	Phosphoric Acid.
Man	180	1.6	0.2	0.033	0.047
Horse	60	2.0	0.4	0.124	0.131
Cow	47	3.5	0.7	0.160	0.197
Goat	22	3.7	0.8	0.197	0.284

THE COMPOSITION OF PROTEINS.

The foundation of our knowledge regarding milk was laid by finding out the composition of a large number of different proteins. These substances are the flesh-growing materials of the body, and form an indispensable part of all the vital body fluids. This work revealed for the first time their great variety, and the fact that a nearly identical percentage composition of their elements (nitrogen, carbon, oxygen, hydrogen, sulphur, and sometimes phosphorus) went along with wide differences in composition and in physical and chemical properties; furthermore, that in the same food material, whether animal or vegetable, two or more proteins of quite different quality were usually found together.

The investigations of research workers showed that a protein is no such simple thing as salt or sugar, but is usually made up of about 18 different complexes, or nitrogen-containing groups, called amino-acids, each of them a complicated structure in itself.

In view of the great differences in the comparative composition of proteins, the question arose: Have the proteins nevertheless about the same food value, as has been assumed, or have they not? If they have not, the principles on which the whole art of animal feeding have been founded in the past are clearly unsound.

The only way to settle this question was to study the effect of each protein, when fed by itself, on growth, maintenance, and production.

Before the work at this Station was begun all experimenters who had endeavored to feed animals on diets composed of pure nutrients had failed. Both mature and young animals promptly declined in weight on such artificial diets. At the present time there is so much clearer an understanding of the influence of food on growth that, merely by changing a single constituent of the diet, one can stop the growth of a young animal at any stage of its development, maintain it for many months without growth, and later cause it to grow again at a normal rate to full maturity. Furthermore, the rate of growth of animals is, to a large extent, subject to direct experimental control.

It was the use of milk, or of milk products, in the earlier attempts to feed animals under experimental conditions that led to the first successes and to the development of the methods of feeding, and these early experiments have given rise to what is to-day the well-founded science of nutrition.

The first attempts at this Station to make an animal grow on a mixture of pure protein, fat, carbo-hydrate, and inorganic salts were no more successful than were those of other investigators; but it was soon found that animals which failed to thrive on artificial diets could be restored promptly to excellent condition by giving them a mixture of dried milk, starch, and lard, and that control animals, fed on a similar diet from weaning, grew normally to full maturity, and re-produced. Although the artificial diets were almost exactly like the milk diets in respect to the kind and proportion of the then-known nutrients, the milk diet was apparently entirely adequate as a food, whereas the artificial diet was wholly inadequate. Wherein this profound difference lay was a mystery. By a process of elimination the conclusion was finally reached that the water-soluble portion of the milk contained something that was essential for life, and later that the fat component contained something that was indispensable for long continued growth. The discovery that milk contained at least two hitherto unsuspected substances, now designated as vitamins B and A respectively, made it possible for the workers at this Station to become pioneers in the study of various problems relating to growth and maintenance. The field of study thus opened has been cultivated by numerous investigators in this country and abroad, with results of far-reaching importance.

The experiments here to be described were made with albino rats, because these small animals are omnivorous, their life span is relatively brief, and their small size permits the preparation of the required quantities of purified dietary constituents in the laboratory without undue expense. To ensure perfect accuracy, it is necessary that the rations shall consist of ingredients that are chemically pure; and to prepare such rations in quantity is very laborious and costly. The question may be asked: Are the results of experiments in feeding rats, or other of the lower animals, applicable to human beings? Although the foods suited to different species of animals may differ widely in their appearance and physical properties, the digestible nutrients contained in them are very much alike in their chemical characters, so that by the processes of digestion quite similar products result from apparently different kinds of food. Such differences as exist are in proportion rather than in kind. Furthermore, the tissues of the different types of animals are chemically even more alike than their foods, and, consequently, the nutritive requirements are in principle much more nearly the same than those unfamiliar with the chemistry of nutrition might suppose.

The conditions in feeding farm animals are necessarily so complex that it is generally impossible to recognise the influence of any individual constituent of the ration. In the experiments with rats, on the contrary, the conditions were so simplified that definite conclusions could be drawn regarding the role of each factor involved. Thus, if two series of animals are fed on mixtures of protein, fat, carbohydrate, and inorganic salts, which are identical except for the kind of protein used, and the animals in one series grow normally whereas the others fail to grow at all, it is obvious that the protein alone is the growth-determining element in the food. By means of large numbers of such experiments, extending over a period of several years, the nutritive values of many proteins, several fats, and some of the inorganic salts have been fixed. Also, a number of combinations of natural food products, both of animal and vegetable origin, which are extensively used in the daily rations of man or domestic animals, have been studied.

CHRISTMAS RECIPES.—The following Christmas recipes were discussed:—*Christmas Cake.*—3 cups flour, 1lb. each currants, raisins, sugar, and butter, $\frac{1}{2}$ lb. lemon peel, 1 cup fig jam, 8 eggs, 2 teaspoons mixed spice, a little nutmeg, $\frac{1}{2}$ cup chopped nuts, 1 teaspoon carb. soda. Dissolve in warm water, and bake 3 $\frac{1}{2}$ hours. *Tomato Paste.*—2 large tomatoes, 2ozs. grated cheese, 4ozs. breadcrumbs, 1 egg, 1oz. butter. Pepper and salt to taste. Skin tomatoes by scalding, cut up, and fry them mixed with rest of ingredients. Fry until thick; take off and put in jars. *Christmas Pies.*— $\frac{1}{2}$ lb. gravy beef boiled tender, 1lb. each currants and raisins 1 $\frac{1}{2}$ lbs. sugar, $\frac{1}{2}$ lb. lemon peel, $\frac{1}{2}$ lb. beef suet, 1 $\frac{1}{2}$ apples, $\frac{1}{2}$ pint brandy, 1 grated nutmeg, essence lemon, mixed spice. Put ingredients through mincer and place in air-tight jar. When ready to bake, use puff pastry. *Christmas Sweets.*—Dissolve 2lbs. sugar with water, add flat teaspoon cinnamon, ground cloves, allspice, 4ozs. glucose. Boil 242 degrees. Pour in bowl, add 3ozs. rasins, currants, almonds, 1oz. mixed peel, 1 dessertspoon brandy. Beat until it creams. Knead well, make into 4oz. balls. (Secretary, Miss D. Spoehr.)

COONAWARRA.

December 13th.—Attendance, 23.

FRUIT DESSERTS.—Paper read by Mrs. L. Redman:—“Prepare fruit, wiping, peeling, coring, &c., as necessary. When stewing fruit of any kind, make the syrup first and when boiling put in the fruit. (By syrup is meant water and sugar, $\frac{1}{2}$ lb. sugar to one pint of water). The syrup should be enough to barely cover the fruit. Directly the fruit is put into the boiling syrup, cook gently so as not to mash the fruit. The longer the fruit cooks, as a rule, it will be a better color. A little sago may be added to the syrup to thicken it. Sago should be well washed and added to the fruit half an hour before dishing or longer. Pour into a mould until cold and it sets like a jelly. Pears peeled and cut in halves or quarters. The pips may be left in as they improve the flavor and appearance. A few drops of cochineal added to the syrup improves the color if time is limited. Dried prunes, pears, apples, apricots, peaches, require different treatment. Wash the fruit carefully, soak overnight, allowing 1qt. cold water to $\frac{1}{2}$ lb. fruit. Boil rapidly with lid off the saucepan until the fruit is quite tender. Add sugar and cook a few minutes longer. Long soaking and rapid boiling give a flavor like fresh fruit. Prunes are improved by the addition of a little lemon juice which should be added at the same time as the sugar. *Green Apricot Tart:* This is an elegant and delicious dish. Put the apricots into a stewpan with one-third of their weight in sugar, and a few spoonfuls of water. Stew gently 15 minutes or until the fruit is tender, then turn out to cool. Make a paste, line the edge of the tart dish, fill with the apricots and cover. Bake half hour. Ice it and serve hot or cold. *Strawberry Jelly:* 1lb. of ripe strawberries, 1 pint of water, 2ozs. sugar, 5 sheets of white leaf gelatine. Put the strawberries, water, sugar, and gelatine into a pudding basin, tie down and steam for 1 $\frac{1}{2}$ hours. Color to a pale pink with cochineal if required, stir thoroughly, but so gently that the berries are not broken. Pour into a damp mould and set aside to cool. Mulberries and small soft fruits may be used in this way. Steamed fruit retains its flavor and color much better than that which has been stewed. *Apricot Gâteau:* One tin apricots, 3ozs. sugar, 1oz. gelatine, 12 almonds. Take the fruit out of the syrup and make up to 5 gills with water, soak gelatine in it 10 minutes, add sugar, and boil 5 minutes. Blanch the almonds and shred, arrange fruit in a mould, sprinkle the almonds over it, strain the syrup, pour over, and set. This can be made with fresh fruit which must be cooked in syrup until tender. *Gâteau of Prunes:* 1lb. of prunes, juice of lemon, 1 pint of water, 3ozs. sugar, $\frac{1}{2}$ oz. of leaf gelatine. Wash the prunes, soak overnight, cook with the water and sugar until quite soft. Next stone them, put back in the pan, add rind and juice of lemon, gelatine, a few drops of cochineal, and boil from 15 to 20 minutes. Rinse out a border mould with cold water then pour in the mixture and leave until it is set. Turn out on to a glass dish and pile whipped cream in the centre. *Peach Tapioca:* 1 can peaches, $\frac{1}{2}$ cup sugar (caster), 1 cup tapioca, boiling water, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ teaspoon salt. Drain peaches, sprinkle with powdered sugar and stand 1 hour. Soak tapioca $\frac{1}{2}$ hour in cold water to cover. To peach syrup add enough boiling water to make 3 cups. Heat to boiling point. Add tapioca drained from cold water, sugar and salt. Cook in a double boiler until transparent. Line a mould or pudding dish with peaches cut in quarters, fill with tapioca and bake in a moderate oven 30 minutes. Cool slightly, turn on a dish and serve with cream. *Pineapple Snow* (Mrs. W. Pounsett): 1 tin of pineapple, about 8 sheets gelatine dissolved in 1 pint cold water, add juice of pineapple and boil. Beat together until light, 2 cups sugar and juice of 2 lemons. Pour hot gelatine over mixture, stir well then add pineapple cut into small pieces. Put in cool place to thicken a little, add stiffly beaten whites of 2 eggs, beat 10 minutes, put

into mould; serve with cream. *Banana Trifle* (Mrs. W. L. Redman): Put banana, then sponge, then banana in dish. Pour jelly over, let set, then pour custard over before it cools, add little butter to it. Cool, decorate, and serve with cream. *Date Trifle* (Mrs. W. L. Redman): Place layer of dates, then layer of cake. Pour over custard. Custard—Beat 1 egg yolk, 1 teaspoon sugar, and 1 cup milk, pour into piedish and place in another containing water, bake until set. Beat egg whites, pile on top. Decorate with dates and cream. *Summer Trifle* (Mrs. Reschke): ½ lb. stale sponge cake, 1 small packet jelly crystals, 1 tablespoon custard powder, ½ pint milk. Lay cake in glass dish, dissolve jelly crystals and when cool, pour over cake. Make custard of powder, milk, and a little sugar, pour over other when cool and jelly has set. A sliced banana put on jelly before adding custard is an improvement. Serve with stewed or preserved fruits. *Summer Pudding* (Mrs. Reschke): Cut thin slices bread, not too new, and line pudding basin with them. See that every part is covered with bread. It may be moistened with milk to make it stick well. Take any kind of fresh fruit and boil with sufficient sugar until cooked, fill basin, cover with plate and stand in cool place until next day. Turn out carefully and serve with cream or custard. *Alpine Pudding* (Miss D. Modistach): Place 8ozs. breadcrumbs in dish, add 2 cups boiled milk whisk, add 2 tablespoons sugar and beaten yolks of 3 or 4 eggs, and essence. Bake ½ hour or until set. Add layer jam or stewed fruit. Beat egg whites stiffly with ½ teaspoon salt and fine sugar to sweeten. Pile on top and brown in oven. *Passion Fruit Delight* (Mrs. O. Skinner): Pulp of 12 passion fruits, 2 tablespoons sugar, 1 dessertspoon gelatine, ½ cup warm water, jar cream. Dissolve gelatine and sugar in water; add to passion fruit; whip cream, and when other is cool stir in; put aside to set. *Spanish Cream* (Mrs. E. G. Alder): Take 1½ pints milk and ½ packet gelatine, 3 eggs, 4 tablespoons sugar, and 1 teaspoon essence lemon. Mix milk and gelatine—dissolved in 1 cup hot water; add egg yolks, stirring quickly until they come to boil; add rest of ingredients and stir briskly for a few minutes; pour into moulds which have been rinsed with cold water; set aside to cool. *Apple Snow* (Mrs. E. G. Alder): 6 pieces sponge cake, ½ pint stewed apples, ½ pint custard, rind and juice 2 lemons, 6ozs. sugar, whites 3 eggs. Make custard with yolks of eggs; place cake in dish, pour custard over; whisk whites to stiff froth, add apples, sugar, lemon rind and juice, whisk all together until white and stiff; pile on top of dish. *Peach Slices and Milk Gelatine* (Miss O. Lear): Open 1 jar preserved peaches, place layer evenly in bottom of round mould and set in place with a little jelly; 1 pint milk, ½ oz. gelatine, 2ozs. or 3ozs. sugar, flavoring; put milk in lined saucepan; add gelatine, sugar, and flavoring; when quite dissolved pour into mould very gently on top of jellied peaches. (Secretary, Mrs. F. Skinner.)

LAURA BAY.

November 14th.—Present: 10 members.

SPONGE CAKES.—Miss L. Blumson read the following paper:—"In making sponges first of all prepare the fire and have it burning for at least an hour before baking the cake, otherwise the oven will not be thoroughly and evenly heated. The oven heat should be a little higher than for fruit cakes, and slightly cooler than for scones. An oven in which scones have just been quickly and successfully cooked is ideal for sponges when it burns down a little. Keep an even, steady heat, and do not open the oven door for at least five minutes, unless absolutely necessary. Extra wood added during baking generally spoils a cake. Prepare the tins and have all ingredients ready, because once the eggs are beaten, the sooner the sponge is in the oven the better. If the eggs are left to stand after being beaten, the cake will not rise so well, and will probably be tough and leathery. Grease the tins and sprinkle lightly with flour. This gives the cake a nice appearance, and it turns out easily. Break the eggs into the mixing bowl and beat with a pinch of salt for a few minutes, then add sugar and beat until the mixture is quite thick, and light in color. Beat for at least from 10 to 15 and up to 20 minutes. The length of beating generally depends on the type of beater used. When the eggs and sugar are sufficiently beaten, add flour and cream of tartar, sifting in a little at a time, and fold in with the lightest possible touch. On no account stir, and finally, with the same light touch, add the soda dissolved in boiling water. Pour at once into tins and bake in a moderate oven for 10 to 15 minutes. When cooked, the sponge shrinks slightly from the edge of the tins, and can be tested by pressing lightly with the finger. If no mark is left the sponge is cooked. Turn out carefully on a cake stand or folded towel, and do not fill until quite cold. Other hints to make sponge cake light: Beat eggs well before adding sugar, and add one to two tablespoons of cold water to the eggs after beating. To save time in beating a sponge, break the eggs on the sugar 1 hour before making. Stir with a fork (do not beat). This melts the sugar and less beating is required. For a sponge roll: Heat the jam and spread immediately it comes from the oven, and the roll never cracks, providing it is done quickly. For chocolate

sponge roll it is necessary to roll first and when cold unroll and spread with butter icing, otherwise the icing cools the cake and makes it crack when rolling. Also the icing seems to penetrate into the hot cake. In the blow-away sponge it is necessary to follow the method very closely, and do not beat eggs first as for other sponges; only beat eggs and sugar 8 minutes. *Recipe:* Half-cup cornflour, two teaspoons plain flour, three eggs, half-cup sugar, one teaspoon cream tartar, half-teaspoon soda. Bake in moderate oven. *Sponge lilies:* 4 eggs, 1 cup each sugar and flour, 1 teaspoon cream of tartar, $\frac{1}{2}$ teaspoon soda, 2 tablespoons cold water. Beat eggs and water for five minutes, add sugar, and beat 10 more minutes. Then add flour and cream of tartar, and lastly soda dissolved in boiling water. Put on greased oven tray in dessertspoonfuls, allowing room to spread. Cook in fairly hot oven seven to ten minutes. Leave slide in the oven and, with a knife, remove one at a time and fold into shape. Fill with whipped cream and jelly. *Rainbow sponge roll:* 6 eggs, $1\frac{1}{2}$ cups each sugar and flour, $1\frac{1}{2}$ teaspoons of cream of tartar, $\frac{1}{2}$ teaspoon soda. Beat as for an ordinary sponge. Take about quarter of the mixture, halve that and color one half brown and the other pink. Cook colors first. When cooked cut into three both colors, and jam brown and pink together alternately. Then cook the remainder on oven slide. Spread with jam and roll quickly round the colored pieces and roll in sugar. *Sponge sandwich with butter:* 4 eggs, $\frac{1}{2}$ cup sugar, 1 cup flour, 1 teaspoon cream of tartar, $\frac{1}{2}$ teaspoon soda. Beat as for other sponges and mix and then lastly stir in 1 dessertspoon of butter dissolved in $\frac{1}{2}$ cup of boiling water. Always use same cup for measurements, and fold flour in gently. Have melted butter ready to put in as soon as the sponge is mixed. This cake will keep moist longer than other sponges."

December 4th.—Attendance, 11.

DAIRYING.—Paper read by Miss Hoffrichter:—"Dairying is a profitable sideline and one which can be managed with comparative ease. The first and most important factor is the care of the cows. Every farmer should have a haystack or a supply of chaff and oats. This the cows need twice daily; first while milking in the morning and next, after milking at night. During the day and after feeding at night, the cows should be grazed in a good grass paddock; in the summer time stubble paddocks are preferable. The water trough should be kept clean and full. Running the cows home to be milked does a good deal of harm. Before milking, the hands and the cow's teats should be washed with warm water, the side of the cow brushed to remove loose hair, &c., which might fall into the bucket. After milking, the buckets must be thoroughly washed, scalded, and placed in a sunny position to dry. The separator should be kept well oiled and free from dust. Use warm water containing soap or borax when washing the utensils and a brush in preference to a cloth; the cloths harbor dirt and cannot clean the crevices. When washed, the utensils are best scalded and drained. The main point in the handling of cream is cleanliness. A patch of rust in the can will deteriorate the cream very quickly and so will the lid close shut overnight. When making butter at this time of the year, procure the coolest place possible and do the work early in the morning. The cream will need to stand at least 24 hours before turning into butter. To commence, salt the pats, butter board, and scale tray in cold water, rubbing well in. The greatest care is necessary to see that the articles used are free from any particle of dirt. After each piece of butter is measured to 1lb. it is placed on the salted board and formed into an oblong shape with the butter pats, thence on to a sheet of butter paper and wrapped up neatly. To keep it firm a good plan is to wrap a wet cloth around it and put it in a cement fireplace if there is no cellar." (Secretary, Miss D. Morrison.)

MORCHARD (Average annual rainfall, 13.59in.).

November 22nd.—Attendance, 10.

MUSIC IN THE HOME.—The following paper was read by Miss McCallum:—"Most people realise the advantage as well as the pleasure of music in the home. It is everyone's duty to try and learn to play some musical instrument, providing they have the opportunity of doing so. Once anyone has attained proficiency it will be a source of pleasure to many other people. To have a really good knowledge of music often proves the beginning of companionship with many people whom one would not meet with otherwise. Those who are fortunate enough to have a thorough musical training realise what an asset it is to home and social life, and the pleasure it gives to others is well worth while the time spent in practising. For those who have no musical instrument in the home, the wireless provides endless pleasure. No matter how tired or low-spirited one is feeling, good music will help to make things more cheerful. Most people derive much pleasure from an evening spent in playing and singing in the home. Young folk of to-day who have so much more opportunity of bringing song and music into their homes are much happier for it." (Secretary, Mrs. C. Schulz.)

MUNDALLA (Average annual rainfall, 19.26in.).

November 30th.—Attendance, 14.

WASHING DAY.—The following papers were read:—Mrs. W. Golding: "I generally rise at 4.45 a.m. on washing day, light the fire, and dispose of breakfast. Then I put the first lot of clothes in the copper and start them boiling. While they are boiling I milk two cows, and by that time the clothes are ready to come out and another lot is put on to boil. After separating, the clothes are rinsed, blueed, and then hung out. Next the colored clothes are put into soak and the birds and pigs fed. The next work is the washing of the separator and breakfast dishes, sweeping the kitchen, washing being finished by nearly 10 a.m. The bedroom is then attended to and a cold dinner prepared. After dinner the clothes are folded, left for about two hours and then ironed." Mrs. M. Sabey: "My method is as follows:—Fill copper, put a good fire under same. Then cut up about 3in. of soap. When soap is dissolved and water hot enough I take out two buckets and put into tub for fine colored clothes. Then put some more water in another tub from copper and soak the white clothes; add some more water to copper and then proceed with the washing of fine colored clothes. This should take about quarter of an hour, by which time the whites are sufficiently soaked. Wash and put in copper and boil 10 to 15 minutes. While these are boiling wash face and tea towels so that they are ready to go in copper when white clothes are taken out. Rinse and blue white clothes and hang on line to dry. By this time towels should be ready to come out. Proceed in same manner. Give the dark colored clothes the first wash in the water in which the towels were rinsed; then take some hot water from copper, add sufficient cold water to make it comfortable to work in, wash until clean, and rinse in clean luke-warm water. I do my washing with two ordinary pieces of soap and usually finish by about 10.30 a.m. I never ring bed quilts; they keep their shape better if hung out wet." Mrs. K. Dinning: "First thing on rising Monday morning I take off the bedclothes and turn the mattress. Then light the fires and sort the clothes. By this time the cows have had their chaff and are ready to be milked. While the milk is being separated and the pigs and calves fed, I make the bed, which has been sufficiently aired. Breakfast is then prepared. Breakfast cleared away and dishes and separator washed, I rub the white clothes, and whilst they are boiling rub all the rest. By this time I take out the first boiling and put second lot on, using cold water and home-made soap. While the second lot is boiling I prepare vegetables and put on the meat to cook. All clothes being put out, I wash out troughs and then scrub floor. If any clothes are dry enough, they are brought in and folded. By dinner time the clothes are all folded ready to start ironing as soon as dishes are washed. I damp all starch clothes, and leave until next day, as they iron much easier and look nicer. After ironing is done and clothes mended, aired, and put away I spend a while in the garden. By this time I have two cows to milk and separator to be washed again." Mrs. D. Kemp: "The ease with which one can accomplish washing and usual household routine depends very much upon the weather. To get an early start it is essential that clothes are sorted and fire set the previous day. Rise about 5 a.m., light the kitchen fire, and then milk cows, feed fowls, &c. Then it is advisable to light the copper so that hot water is ready after breakfast. Before commencing to wash, dismantle separator, pack dinners, and clear the table. Next wash out tablecloths, pillow slips, handkerchiefs, &c., having previously added borax and Witch soap to luke-warm water in copper. While the first copperful is boiling, quarter to half-hour, rub out the second. When the first copperful is ready, drain well, rinse, blue, and starch, then hang out to dry while lot No. 2 boils. It is most convenient to have lunch at this period, and after making the beds, I resume washing colored clothes and woollens, using the Witch soap jelly already prepared. Change the water frequently or else wash this group twice. After putting through rinsing water and blue, hang stockings and silk underclothes on limbs of a large almond tree under which I wash, as they are then in the shade and there is no fear of pegs causing runs. Other garments go on the line. Dirty dungarees, if very old and very dirty, I put in the copper, but if possible I prefer to wash in the tub and save the copper water for scrubbing buckets, brooms, troughs, &c. As a rule there is then time to wash dishes and separator, sweep kitchen, and bring in clothes dry enough to fold for ironing. Dinner is easily arranged, consisting either of Sunday left-overs or perhaps cold meat and boiled rice, cinnamon bread, or some other simple dish. I wash-up while the irons are heating and then iron and fold."

SIMPLE SUMMER DESSERTS.—Milk Jelly. (Miss M. Knowling).—Sweeten 1 pint of cold milk, dissolve 2 dessertspoons of gelatine in hot water and add to milk. Set in mould half hour, serve with fruit. *Cinnamon Bread* (Miss M. Kemp).—Dip fingers of bread in egg and milk, fry and sprinkle with cinnamon and sugar. *Rice or Rhubarb* (Mrs. H. Wiese).—Add cinnamon and sugar, currants or sultanas to boiled rice. Add sultanas, lemon and ginger, sage, to stewed rhubarb. *Poor Man's Biscuit* (Mrs. Sabey).—4 cups flour, 1½ cups sugar, 1 cup dripping or butter, ½ cup milk, 1 teaspoon

soda, 2 teaspoons cream of tartar. *Method*: Put sugar, milk, and soda in saucepan, boil until all melted, stand to cool, then mix with flour and butter. Roll out thin and bake in hot oven until golden brown. One tablespoon custard powder added to flour improves mixture. *Soap Recipe* (Mrs. H. Wiese).—6lbs. fat, 2galls. water, 2 table-spoons borax, $\frac{1}{2}$ lb. resin, $\frac{1}{2}$ bottle cloudy ammonia, 1 large packet Lux, 1 tin caustic soda; add cloudy ammonia and Lux when boiled half-hour. *Hints*.—A pinch salt added to rhubarb saves sugar. Add 1 lump sugar to cabbage water to improve flavor. Spread coffee grounds on stove to drown odor of onions, cheese, or fish. (Secretary, Miss M. Kemp.)

PARRAKIE (Average annual rainfall, 14.64in.).

November 28th.—Attendance, 14.

HOME NURSING.—Paper read by Mrs. W. Herbert:—"Bruises are not as a rule serious, but they are painful. The best treatment is to apply pads of cotton-wool soaked in cold water to relieve pain and prevent discoloration. *Cuts*.—The flesh should be pressed up towards the cut to encourage bleeding, which will help to clean it. Then it can be bathed with cold water and disinfected and bound with a bandage. On no account should adhesive plaster be put right on it; a cut needs frequent examination to make sure that the healing process is going on satisfactorily. *Scalds* should be treated by the application of cold compresses which at once will ease the pain. The child should be treated for shock by giving a warm bath and a little light nourishment. He should be kept warm and quiet until the arrival of the doctor. It is important to keep as calm as possible, because the child may take fright from the mother's alarm. *Grazes* continuously occur on the knee and need careful treatment, especially if the child has fallen down on the road. Any wound, however slight, that has been in contact with soil needs very thorough disinfecting. First wash the wound very thoroughly, and when clean, finish the process with iodine, friar's balsam, or any reliable antiseptic. Iodine is the disinfectant commonly recommended, but it may burn the surrounding skin; friar's balsam has no such disadvantages. When the wound has been thoroughly disinfected, smear some antiseptic ointment on a piece of lint and strap loosely in place. Grazes heal more rapidly if the surface is kept soft. If a hard scab is allowed to form, there is the risk that it will crack and be knocked off, and the trouble start afresh." (Secretary, Miss J. Halliday.)

PARILLA (Average annual rainfall, 14.01in.).

December 17th.—Present: 17 members.

SUMMER SWEETS.—*Lemon Snow* (Miss P. Foale).—Boil together $\frac{1}{2}$ cup sago, 4 cups water, 1 cup sugar, and grated rind of 2 lemons. When boiled, add juice of 3 lemons; when nearly cold add well-beaten whites of 4 eggs. *Charlotte Russe*.—Line a mould or basin with strips of stale sponge cake, each piece overlapping the other. Have made 1 pint jelly, and pour some of this over cake. Beat 1 cup of cream lightly, add to remainder of jelly, which should be cold, beat well and pour in mould. Turn out when set and decorate with strips of almonds, or decorate mould with cherries and angelica before putting in cake. *Siberian Cream and Dates* (Mrs. F. Kerley).—2 dessertspoons gelatine, $1\frac{1}{2}$ cups milk, $\frac{1}{2}$ cup hot water, 2 dessertspoons sugar, dates, 2 eggs, vanilla essence. Beat yolks of eggs and sugar together. Heat milk to boiling point, stir in eggs, and cook until mixture coats the spoon. Leave to cool; flavor with essence. Add gelatine dissolved in hot water, beat whites of eggs until stiff. Whisk into the mixture, have ready a fluted mould lined with dates; pour in mixture when it is thickening. *Strawberry Trifle* (Miss E. A. Colwill).—1 stale sponge cake, 2 eggs, 1 jelly crystal, $1\frac{1}{2}$ pints milk, 3 dessertspoons cornflour, $\frac{1}{2}$ cup sugar, 1lb. strawberries. Layer the sponge cake at the bottom of the dish, pour over it the melted jelly crystal, when cool, then add a layer of strawberries, put custard on top of this, and then repeat another layer, having custard on top. *Custard*.—Boil the milk, add yolks of eggs and cornflour, which must be previously mixed with cold milk, and bring again to a boil. When cold, pour over cake and fruit, beat the whites of eggs to a stiff froth, and place on the top of the trifle. *Apple Snow* (Mrs. H. G. Johnston).—Take the pulp of 2 baked apples, 1 cup of sugar, the whites of 1 egg, and beat well until very light and fluffy. This is nice served with stewed cold apple, and also makes a nice dressing for a cold apple pie when cream is scarce. Line a pie dish with pastry. Partly bake, then pile the snow on to the pastry, put back in oven until snow is a nice light-brown color. *Lemon Pudding* (Mrs. Les. Foale).—Beat yolks of 2 eggs with $\frac{1}{2}$ cup sugar, add piece of lemon, and sift in 2 tablespoons cornflour. Stir in 1 pint of boiling water, stand on stove, stirring until it thickens, then pour into a buttered pie dish. Beat up whites, adding $\frac{1}{2}$ cup sugar, pile on top of pudding, and put in oven to brown. *Duncan Pudding* (Mrs. H. C. Colwill).— $\frac{1}{2}$ cup sugar, $1\frac{1}{2}$ tablespoons cornflour, mixed with the juice of large lemon, 2 cups boiling water, bring to the boil and stir into it the snow made by the whites of 2

eggs. Then make custard with yolks of eggs and pour round when cold. *Peach Blanmange* (Mrs. D. Smitham).—10 peaches, 3 dessertspoons cornflour, 2 cups cream, 1½ cups milk, few almonds. Put 1 cup cream, 1½ cups milk, and 3 tablespoons of juice from peaches on to boil; when boiling, add cornflour, mixed with a little more juice, then pour in wetted mould, put away in cool place. When set, turn out in rather large bowl, put peaches around side down, whip remainder of cream, put a little in each peach, and over blanmange, then put almonds cut small and browned over fruit. *Sago Cream* (Mrs. H. C. Colwill).—Put 2 heaped tablespoons sago into a breakfast cup of milk, and boil for a few minutes. Add the beaten yolks of 2 eggs, 2 tablespoons sugar, and another cup of milk beaten together. Stir over the fire until it thickens. Take off and add the beaten whites of the eggs and a little flavoring. Pour into a wet mould and serve cold. *Lemon Sago Jelly* (Mrs. H. C. Colwill).—1 cup sago, 5 cups water, 2 tablespoons golden syrup, 2 lemons, 1 cup sugar. Boil sago in water until clear, add other ingredients, boil a few minutes, add a few lemons, pour in wet mould, serve cold. *Apple Snow* (Miss Sheila McCormack).—Take 6 large apples and reduce them to a pulp by passing them through a sieve, flavor and sweeten them according to taste. Whisk the whites of 6 eggs and strew upon them 2 tablespoons of sugar. Beat the apples until they are a froth, then mix them with the beaten whites of eggs until they look like stiff snow; now pile them on a glass dish in rough pieces, and garnish with tablespoons of red jelly. Stick a sprig of green on the top. (Secretary, Mrs. R. Welden.)

PINNAROO (Average annual rainfall, 14.57in.).

November 1st.—Attendance, 48.

DIFFERENT WAYS OF USING GELATINE.—Paper read by Mrs. Mattiske:—"Half the fascination of gelatine cookery is the interest it provides in making delightful dishes out of trifles of left-over foods. Left-over salads are usually wasted, but the housewife who knows what gelatine can do takes some salad dressing and adds perhaps scraps of meat to the salads, and has for such a little effort a dish of rare attraction. Gelatine is greatly influenced by temperature. In compiling recipes, the object has been to balance the ingredients, particularly the gelatine, to ensure the dish setting under normal conditions, without an icechest. If the weather is very hot and ice not available, the gelatine content should be slightly increased or less liquid used. Gelatine should never be heated with milk, or added to hot milk, for it causes the milk to 'curdle.' This is not a curdle in the strict sense; merely a division of the curd and whey due to using the milk too hot. This so-called curdling is in no way detrimental; the milk remains perfectly sweet. To avoid this difficulty, first dissolve the gelatine in hot water, then add to the cold milk. *To Garnish Gelatine Dishes.*—Use clear jelly liquid, sweetened and flavored for dessert, &c., and seasoned for meats, salads, and savories. If the mixture for the dish is not clear, make a little by dissolving ½ teaspoon of gelatine in a little hot water, add cold water to make ½ cup, flavour as required. Cover the bottom of the mould with a little of the liquid. When firm, arrange the garnish to make a decorative pattern; then cover with remainder of the clear liquid; when set, arrange the rest of the ingredients and pour in the jelly liquid. *To Remove Gelatine Dish from the Mould.*—Run a pointed knife around the edge of the dish to just loosen, immerse the mould in warm water for a few seconds, dry with a cloth, place a dish or plate on top and turn upside down. Shake the mould gently; if the jelly will not leave the mould, immerse in warm water and repeat the process. A doyley placed over the top of mould will enable the shape to be placed in position on the plate or dish. Gelatine contains a great deal of protein, the most valuable of all food elements. It therefore enriches the food value of every dish of which it is an ingredient, and, because of its colloidal properties, facilitates the digestive process, thus it is of great value in the dietary."

RECIPES.—*Salmon in Jelly* (6 servings).—Ingredients: 2 dessertspoons (½oz.) gelatine, 1 small tin salmon, 1 cup cold water, ½ cup hot water, ½ cup vinegar or lemon juice, 1 hard boiled egg, salt and pepper. Method: Take tin of salmon and open into basin, break up with a fork, finely dissolve gelatine in hot water, adding vinegar or lemon juice, salt and pepper, and cold water. Pour a little into a round mould or cake tin. When firm, arrange slices of hard-boiled egg, pour over a little liquid. When the jelly liquid is thickening, stir in salmon, and pour into prepared mould. Garnish with shredded lettuce, slices of lemon and salads available, vinegar or lemon may be omitted from ingredients, and 1 cup of water used instead of ½ cup. Serve dish with vinegar or slices of lemon. *Asparagus Tip Salad* (6 and 7 servings).—Ingredients: 3 dessertspoons gelatine, 1 tin asparagus tips, white heart of 2 sticks of celery, 1 lemon, water, mayonnaise dressing, lettuce. Method: Drain liquor from asparagus, measure and add water to make 2 cups liquor and water together, add salt, pepper, lemon, and celery cut in small pieces. Bring to boiling point, dissolve gelatine in 1 cup hot water. Add to liquid, line mould with tips, cut up remainder

of tips, mix with celery liquid and pour into mould. When set, serve with lettuce and mayonnaise dressing. *Beetroot Mould* (6 servings).—Ingredients: 2 dessertspoons (1oz.) gelatine, 2 average-sized beets (cooked), $1\frac{1}{2}$ cups hot water, $\frac{1}{2}$ cup vinegar, pepper, salt and sugar to taste. Method: Peel and slice beetroot, line mould with the slices, fill the centre with small pieces of beetroot, dissolve gelatine in hot water, add sugar, salt, pepper and vinegar. Leave to thicken slightly, then pour over beetroot, served garnished with shredded lettuce and sliced tomato. Serve with mayonnaise dressing. If liked, more vinegar and less water in proportion may be used in this recipe. *Christmas Plum Pudding* (9 and 12 servings).—Ingredients: 3 dessertspoons gelatine, 3 cups milk, $1\frac{1}{2}$ squares chocolate or 3 tablespoons cocoa, $\frac{1}{2}$ teaspoon vanilla, $\frac{1}{2}$ lb. chopped nuts and lemon peel, $\frac{1}{2}$ cup raisins, $\frac{1}{2}$ cup dates or figs, $\frac{1}{2}$ cup currants or chopped ginger, $\frac{1}{2}$ cup sugar, pinch salt. Method: Place milk, chocolate or cocoa in saucepan, bring to boiling point, add all ingredients except gelatine and boil for 5 minutes; let cool. Dissolve gelatine in $\frac{1}{2}$ cup hot water, add to mixture, stirring all well together, pour into a wet mould, decorate with holly and serve with cream or custard. *Bananas in Jelly* (6 servings).—Ingredients: 2 dessertspoons gelatine, 1 cup hot water, 1 cup cold water, 2 lemons, 4 dessertspoons sugar, 6 bananas. Method: Dissolve gelatine and sugar in hot water, add lemon juice and finely grated rind of $\frac{1}{2}$ lemon, add cold water, strain. Pour a little of the liquid into the bottom of mould. Arrange bananas cut in fine rings. Cover with more banana and cover with jelly. Continue this way until the ingredients are used. When set, serve with cream or custard. *Pineapple Marshmallow* (6 or 7 servings).—Ingredients: 2 dessertspoons gelatine, 1 tin preserved sliced pineapple, few crystallised cherries, hot water, sugar, cochineal. Method: Dissolve gelatine in hot water, drain syrup from pineapple, add dissolved gelatine to syrup and water to make 2 cups liquid, sugar to taste. Place a little liquid in the bottom of a mould; when firm, arrange a slice of pineapple with a cherry in the centre. Pour over a little more liquid. When firm, coat the sides of the mould with a jelly and place the slices of pineapple and cherries in position. Cut up the remainder of the pineapple and cherries into the jelly, color with a few drops of cochineal, beat thoroughly until thick, then fill the mould. Serve with cream or custard. (Secretary, Mrs. F. Atze.)

RENDELSHAM.

December 6th.—Present: 14 members.

CHRISTMAS COOKING.—Paper read by Mrs. Bignell. Christmas is a time of feasting as well as rejoicing, so in most homes one of the main things is the cooking. Christmas cakes, puddings, and biscuits can be made before Christmas. If there are several children in the family, a plainer cake and pudding is very nice and is enjoyed just as well as a very rich one. Colored icings and scented lollies, also glazed fruits help to decorate. Nuts or nutmeg can be grated, a sprig of holly and rings of silver cachous put on when the pudding is turned out is very effective, or spirits poured over and then lit. *The Turkey or Poultry.*—The turkey must be in good condition and not old. Fill the body with stuffing made out of bread crumbs, parsley, and a white onion and bind with an egg; stuff the craw with mince meat and season with herbs, baste as often as possible, and within $\frac{1}{2}$ an hour or 20 minutes before finished put $1\frac{1}{2}$ lbs. of sausages and rings of bacon around the turkey; pour off fat and make gravy in the usual way. Green peas, cauliflower, apple sauce, baked and boiled potatoes, also if a piece of pork or roast beef is cooked a Yorkshire pudding can be baked in the fat around the meat; rings of lemon can be added if liked. *Christmas Pudding.*—Take $1\frac{1}{2}$ lbs. flour, $\frac{1}{2}$ lb. bread crumbs, $1\frac{1}{2}$ lbs. of suet, $\frac{1}{2}$ lb. sugar, $1\frac{1}{2}$ lb. stoned raisins or muscatels, $\frac{1}{2}$ lb. currants, $1\frac{1}{2}$ lbs. sultanas, $\frac{1}{2}$ lb. of mixed candied peel, $\frac{1}{2}$ lb. ground almonds, $\frac{1}{2}$ lb. of treacle, 5 eggs, $\frac{1}{2}$ pint of milk, 1 teaspoon of ground ginger and cinnamon, the grated rind and juice of 1 large lemon, 3 teaspoons baking powder. Chop the suet very finely and mix with sifted flour, then add bread crumbs and grated almonds. Clean the fruit and cut the muscatels or raisins into small pieces, chop the candied peel finely, and put into the pan with the ginger, cinnamon, and baking powder. Mix ingredients together, beat up the eggs, warm the treacle and mix both together, then put the milk on to boil. Pour the treacle and eggs into the pudding, mix with a wooden spoon, add the milk gradually, taking care not to make the mixture too wet, grease the pudding basins, and dust with sugar, then fill to within an inch from the top. Place a piece of greased paper on top and tie down with a cloth; boil for 6 hours or steam for 7. *Plum Pudding.*—Take 1 cup each plain flour, bread crumbs, currants, raisins, and sultanas mixed, 1 lightly filled cup of chopped suet, or $\frac{1}{2}$ of dripping, with part butter if liked; 1 small cupful sugar, a good $\frac{1}{2}$ cup of water or milk, into which a medium teaspoonful of carb. soda is dissolved. This makes a nice Christmas pudding. If all butter is used, steam in a basin from 2 to 4 hours, longer if preferred. *Jellies.*—Jellies are usually very mild; the

flavor of most jellies can afford to be strengthened, making a lot of difference to the jellies. Cherries, small lollies, or pieces of fruit can be put in the jelly just before it sets. *Trifles.*—*Imitation Trifle.*—Take 3 or 4 stale sponge cakes, cut lengthways, spread with jam, cut in halves, and pile in glass dish. Dissolve one .3d. packet of jelly in hot water and pour over the sponge cake and leave to set. Make 1 pint of custard and pour over it; can be decorated with almonds or any glazed fruits. *Norwegian Trifle.*—Take 1lb. cooking apples, stew and sweeten to taste. Take $\frac{1}{2}$ lb. tea rusks, crush them to a powder, and fry in a little butter. After this, place a layer of apples and a layer of tea rusks in a glass dish alternately, until the amount is used up, and cover with whipped cream. Passion fruit can be used in most trifles. *Lamingtons.*—1 cup butter, $1\frac{1}{2}$ cups sugar, 1 cup milk, 3 cups flour, 1 soda, 2 cream tartar. 4 eggs, vanilla. Beat butter and sugar to a cream, add eggs, well beaten, then milk with soda dissolved in it. Cut into pieces, cover with 1lb. icing sugar, $\frac{1}{2}$ lb. butter, add $1\frac{1}{2}$ tablespoons boiling water, 4 teaspoons cocoa, vanilla to taste; roll in cocoanut. *Ribbon Cake.*— $\frac{1}{2}$ cup each sugar and butter, 1 cup milk, 2 cups self-raising flour, 2 eggs. Beat butter and sugar to a cream, add eggs well beaten, then

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

DELIVERY.—CHICKS—February and March.
EGGS—January and February.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

milk and flour. Divide into three—one plain, color one with cocoa, another with cochineal. Cook in sandwich tins, ice when cool. *Almond Icing*.—1lb. sweet almonds pounded or 1lb. almond flour, ½oz. bitter almonds, also pounded, 1lb. icing sugar, juice of ½ lemon, a little rose water, 1 egg. This icing when spread on the cake should be left for 3 days. *Mock Cream*.—2 tablespoons each butter and sugar, well beaten to a cream, then add 1 tablespoon milk, beaten well in, then 1½ tablespoons boiling water, vanilla to flavor. Beat until like whipped cream. If using essence or cochineal, use less water. *Christmas Cake*.—Take 1lb. butter, beat to a cream, then add 1lb. sugar, when well mixed, add ½lb. stoned raisins, ½lb. currants, ½lb. sultanas, 6ozs. lemon peel chopped fine, 6 bitter almonds, 1oz. sweet almonds, juice of lemon and grated rind, a pinch of powdered cloves, 2 pinches of powdered cinnamon, a little nutmeg, 3 cups flour, the yolks of 8 eggs beaten with a wine glassful of brandy. As each article is added, the mixture must be well stirred. Lastly, stir in the whites of eggs, beaten to a froth, and continue beating the mixture rapidly for 20 minutes; then put in a buttered paper mould and bake for 3 hours in a moderate oven. (Secretary, Mrs. E. Andrews.)

TANTANOOLA.

December 6th.—Attendance, 13.

PUDDINGS.—Miss Burchard read the following paper:—"Puddings which contain suet, butter, or dripping are usually boiled in a cloth or steamed in a greased mould, and are both nourishing and wholesome for the cold weather, but for summer a lighter diet should be provided, and those which can be prepared in the morning and served cold for dinner are usually more appetising on a hot day. Baked custard or pudding made chiefly with milk and eggs require a slow cooking, and a basin of cold water placed in the oven prevents the mixtures boiling and therefore curdling. Gelatine is a great help in preparing a small quantity of fruit or in the making of a variety of dishes. Stale cake, or a sponge or a light mixture, with a small quantity of sweet stewed fruit, can be made into a nice trifle by pouring the stewed fruit over the slices of cake, followed by a boiled custard. Sprinkle with desiccated cocoanut and serve with cream. *Cream Sago*.—Put a heaped tablespoon of sago and a breakfast cup of milk into a saucepan and boil for two or three minutes. Add beaten yolks of 2 eggs, 3 small tablespoons of sugar and another cup of milk, beaten together; stir over fire until it thickens, then take off and add the whites of eggs beaten to stiff froth, and a little flavoring. Beat all well, then pour into wetted mould, turn out, and serve cold. *Spanish Cream*.—1 quart milk, 2ozs. gelatine, 1 cup sugar, 4 eggs, essence to taste. Soak the gelatine in milk or water for half-hour; then add to it the rest of the milk (boiling); stir over the fire, boil 1 minute, add the yolks of eggs beaten with the sugar, and stir until boiling again; lastly add the whites beaten well. Pour into a mould when cold, turn out, or set in a glass dish and it is ready to serve when cold." *Fruit Sago Mould*.—Soak 4ozs. washed sago in 1½ pints cold water, simmer gently until thick and transparent. Stew 1lb. sliced fruit with rind and juice of lemon to a pulp, add sugar to taste. Mix apple and sago, pour into a wet mould; when firm, turn out and serve with custard or blanc mange. *Queen Pudding*.—About 2 cups of bread in dish, soak in milk; add sugar to taste and the beaten yolks of 4 eggs. Bake slowly in oven; remove and spread with raspberry jam and pile the well-beaten whites of 4 eggs with a little sugar added over the pudding and brown slowly in cool oven." Miss Burchard tabled samples of the puddings made from her recipes. (Secretary, Mrs. E. Telfer.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

South-East (Lower), at Tantanoola, Wednesday, April 11th, H. M. Kennedy (Secretary).

Dairying, at Milang, Wednesday, May 9th, I. E. Yelland (Secretary).

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

“Twin Lamb” Disease.

The Chairman of the Governing Council of Roseworthy Agricultural College has received from the Principal (Dr. A. R. Callaghan) a statement setting out the experiments which are being conducted at the College in connection with the disease in sheep known as “twin lamb” disease.

He states that following last year's feeding trials with pregnant ewes a further experiment is planned for February and March, using ensilage and oats as contrasting rations, but supplemented with licks.

Losses of pregnant ewes from “twin lamb” disease are of world-wide occurrence, and the malady has been under investigation in recent years at a number of centres. In 1930 and 1931 experiments to discover its cause were conducted at Roseworthy College by Messrs. A. R. Hickinbotham and W. G. Bennett, and reports were published in the *Journal* of the Department of Agriculture, the conclusion reached being that a deficiency of lime was the cause, or, at least, an important predisposing factor.

By a recent mail a letter has been received from the Chief Chemist of the Rowett Research Institute, Aberdeen, Scotland, describing experiments conducted there to test the importance of lime-deficiency in this disease, and the results fully confirm the results obtained at Roseworthy. Two lots, each of four ewes, were kept over a full year on a ration designed to be satisfactory in every way except that it was deficient in lime. To one group a lime lick was supplied to make good this deficiency. In the lot receiving the lime lick no trouble was experienced, and seven healthy lambs were reared. In the group receiving no lime, two ewes died during pregnancy, and the other two were only brought through lambing by discontinuing the experiment and placing them on corrective food. Two lambs were reared from this group. *Post mortem* examinations of the ewes that died showed the cause was “twin lamb” disease.

Losses from this cause are most common in a dry season such as this promises to be, when no greenfeed is available, and especially when hand-feeding is adopted. As a result of feeding trials carried out by Mr. Whicker at the College last season, there is reason to believe that the feeding of ensilage may be of some value as a corrective, especially if some lime is supplied in the form of licks in addition. A further trial will be conducted this year, and in it ensilage will be contrasted with ensilage plus calcium lick. The results obtained at the College show that cases are very difficult

**"YOU CAN
DRIVE AS
FAR AND FAST
AS YOU LIKE
ON THESE
TOUGH TYRES"**

Today, when cruising speeds are in the forties, and the speedo sometimes shows a 70 or 80—its a fine thing to be able to ride on a tyre you can "fit and forget." And Perdriau is all of that.

Its tread rubber is *double toughened* to withstand the terrific road-abrasion of speed and sudden braking. Its casing cords are completely insulated against friction and have a reserve of vitality that resists every stretch or strain—even of continual cornering at speed. Drive as hard as you like—Perdriau matches the best your car can do and gives safe and troublefree service for thousands of extra miles. Your local dealer can now supply all sizes at the lowest prices for years.

The Perdriau tyre is a product of Dunlop Perdriau Rubber Co. Ltd. — the largest manufacturing organisation in Australia, employing 5,000 Australian workers and making every variety of high class rubber goods.

Perdriau
DOUBLE TOUGH

to cure, owing to the extensive disorganisation of the system that has taken place before sickness becomes apparent. Such cases sometimes respond to drenches containing lime (1 teaspoonful slaked lime or calcium chloride) or lime and sugar (½ lb.) to supply some food, in half to one pint of water; but generally the death of the lambs *in utero* causes the death of the ewe. In these circumstances preventive measures are important, namely, ensuring an adequacy of lime together with exercise and some green pickings, if possible. By keeping lime in the drinking troughs nearly one-half of the lime requirement will be obtained from the water, and this is probably sufficient in most cases (with exercise) to enable the flock to pull through without trouble. Experiments to devise a satisfactory lick are at present in progress at the College.

Smut in Oats.

“Wynarka” asks how to combat smut in oats, and Mr. R. C. Scott, Supervisor of Experimental Work, says that there is no practicable treatment on farms which would prove entirely effective. For small quantities and with special facilities the grain may be subjected to the hot water treatment, which attacks the spores which may be under the husk, but with ordinary pickles these spores would escape. However, pickling with either a powder or solution will destroy all spores of the disease that happen to be on the outside of the grain, and therefore will prove fairly satisfactory, but not absolutely perfect.

Of the ordinary pickles formalin used at a strength of 1 lb. to 40 galls. of water is the most effective, as it has a more penetrating action than others, but if the grain is to be sown on dry land has the disadvantage of affecting germination in the same way as it does wheat.

Should the oats be sown on damp soil, the use of formalin is recommended; but if seeded dry, pickling with copper carbonate would be less dangerous. On the average, oats will require approximately 2 ozs. of copper carbonate per bushel to be thoroughly coated with the powder.

Californian Cape Barley.

“Maitland” reports that he intends to sow Californian Cape Barley. He asks if it is a soil impoverisher, and is it likely to revert to the old “bluish” Cape. Mr. W. J. Spafford (Deputy Director of Agriculture) says land which is in good heart does not suffer because of Californian Cape Barley being grown on it, provided that it is grown in its proper order. In any rotation in which Californian Cape Barley is one of the crops, it should always be the last crop grown before resting the land as pasture, or preparing it as bare fallow. For instance, if the three cereals—wheat, oats, and barley—are being grown, the order of cropping would be:—

Fallow—Wheat—Oats—Barley—Pasture—Fallow; or

Fallow—Wheat—Oats—Pasture—Barley—Fallow.

If the land is rested after Californian Cape Barley, or worked as bare fallow, no ill-effect will be noticed from the crop, no matter how heavy the yields secured.

Not one of the strains of Californian Cape Barley that has come under the notice of the Department of Agriculture has reverted to the old steely blue Cape Barley, and there is no reason to expect such a change. The samples imported are of a yellowish color, and when they arrive have a clear, bright appearance, which unfortunately they quickly lose when grown on most soils in this State. Although the brightness is lost, and the grains grown here become more or less muddy in appearance, there is no tendency to become blue.

All samples of Californian Cape Barley inspected contain some admixture of different kinds of barley, but the proportion of bluish grains is very low in all strains, and absent altogether from most of them.

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. G. Quinn, Chief Horticultural Instructor.]

Vegetable Growing Queries.

"Lameroo" asks: "*What is the cause of the fruit of trombones failing to set?*"

Reply—Trombones frequently fail to set fruits during the earlier period after flowering begins, and the plants are still very vigorous. These plants are monoecious, that is, they bear two types of flowers on the same plant—male and female. The male flowers are the smaller ones with thin petals, and are borne on a slender stalk. The female flowers have thicker petals which are carried on the top of the ovary—or embryo trombone. In the earlier part of the flowering period nearly all the blooms are male flowers, and consequently no fruits are formed. Often when a few of the female flowers are ready to receive pollen, no male flowers are available with viable pollen, and they soon pass the stage of receptivity. In a home garden artificial conveyance of pollen from the male flowers to the stigmas of the female blooms may be effected by means of a soft brush or rabbit's tail or paw. As the season advances, there would appear to be a more simultaneous opening of male and female blossoms and pollination is effected more readily through insect intervention.

Lettuce Growing.

"Lameroo" asks: "*What is the best variety of lettuce for summer and early autumn?*"

Reply—The Drumhead or Malta type of cabbage lettuce is most favored for general crops. There is no variety of lettuce known to me that will grow and develop a sweet, crisp foliage during the dry hot season in the open country of this State, even if planted under a bush house. If seeds are sown in a box in mid-February, and kept growing in a shaded position so as to have them ready to plant out in early April, as the weather is cooling down, you may develop fair hearts during the winter and spring seasons. Seeds sown in an outdoor bed in June, and planted out as soon as the plants are large enough, should carry on a supply into October or November, but as the weather becomes hot, the leaves invariably develop a bitter taste, and the plants run to seed. Lettuces, like all vegetables grown for their leaves, require ground rich in organic matter. Well-rotted animal manures should be dug in and mixed with the soil preparatory to planting out the crop. Whilst the plants are growing, liquid manure made by steeping fresh cow manure in water or dissolving sulphate of ammonia—1oz to a gallon of water—may be given once or twice a week, or by sprinkling blood manure at intervals of several weeks around the plants on the broken surface and watering it into the land. All of these are nitrogenous and prove great aids to leaf growth. It is questionable whether superphosphate is of any great value in producing a lettuce crop.

Carrots and Parsnips.

"Lameroo" asks: "*Is it advisable to put super in the row when sowing seeds of lettuce, carrots, and parsnips?*"

Reply—These crops should be sown on land which is naturally loose or has been made so by the incorporation of organic matter a year or two previously. In general terms, animal manures should not be applied to land which will be almost immediately sown down to these root crops, and, as a rule, no fertiliser is sown directly with the seeds of carrots and parsnips.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Bugle Agricultural Bureau reports death of cow. Symptoms: Off food and drink. jaws stiff, had been chewing bones, and appeared to be more or less paralysed.

Reply—The death of the cow was due to Botulism (dry bible). This disease is due to a poison (toxin) manufactured by a germ in the carcasses of animals which have died and become infected with the germ. The cows get the germ by chewing bones or portions of carcasses. The craving for bones is due to a want of mineral matter in the feed, and the more intense this craving is, the greater is the mineral want. As soon as the feed dries, the mineral matter in it becomes less and less, until during the middle and end of the dry period, the mineral content of the dry pasture feed is at its lowest. The disease can be prevented by:—(1) Better feeding, *e.g.*, good quality chaff and oats. (2) The removal of all carcasses and bones of animals from the paddocks. (3) The provision of a mineral lick. The following is recommended:—Dicalcic phosphate (35-37% P_2O_5), 45 parts; coarse salt, 40 parts; molasses, 5 parts; water, 10 parts. 4-5ozs. of this mixture should be fed daily to each cow. A less effective mixture is as follows:—Superphosphate, 45 parts; lime, 15 parts; coarse salt, 40 parts. The same amount could be fed daily.

Truro reports death of cow. Symptoms: Almost total cessation of milk flow, blood from all teats, and udder very pendulous.

Reply—The cow had an attack of acute gangrenous mastitis (or mammitis), her death being caused through the absorption into her system of toxic (or poisonous) products formed in diseased udder. Treatment of acute mammitis must be commenced promptly and the cow after being isolated in comfortable quarters given a laxative dose of medicine (*e.g.*, Epsom salts, $\frac{1}{2}$ -1lb.; molasses, $\frac{1}{2}$ pint; ground ginger, 2ozs.; warm water, 1 quart) followed by 1oz. doses of saltpetre daily in drinking water for a few days. The udder should be fomented at frequent intervals with hot antiseptic solutions (such as 2 per cent. lysol solution) and a little camphorated oil rubbed in after each fomenting to prevent chill. If the udder is dark and discoloured and gangrene threatens, frequent bathings with a solution of $\frac{1}{2}$ lb. Epsom salts dissolved in 1 quart of hot water will often be found very beneficial. The affected quarters should be gently stripped out as completely as possible at frequent intervals (hourly or two-hourly if possible). If gangrene supervenes (when the udder tissues will become bluish-black in color, swollen and dead in appearance), it is necessary to lance the tissues at several places and bathe frequently with antiseptic solutions. Antiseptic tonics such as tincture of iron, 1 tablespoon, should also be given 3 or 4 times daily in a quart of water.

Carahue Agricultural Bureau reports horse with bad cough.

Reply—Give the horse 1 tablespoon of Fowler's solution of arsenic in a small damped feed night and morning for 14 days. Arrange to give the horse a ration of long hay before each feed. This will check any tendency there may be to bolt his chaff.

Black Springs Agricultural Bureau reports young pigs weak in hind legs.

Reply—Give a dose of 1oz. Epsom salts per pig, well diluted in milk or slop feed. Subsequently provide a liberal allowance of skim milk in the daily ration if available. If not, give up to 5 per cent. of meat meal daily; 1 to 2 teaspoons of cod liver oil per pig should also be given daily in the trough feed. Allow the pigs to run out during the day and keep in warm dry quarters at night.

MALLEE FARM COSTING—FARM No. 1.

(Continued from Page 791.)

[By ARTHUR J. PERKINS, Director of Agriculture.]

PART III. (continued).—STUDY OF MALLEE FARMING COSTS.

C. COSTS AND RETURNS OF A MALLEE FARMER'S FLOCK.

I. Introductory.

Both on the Murray lands and on Eyre's Peninsula the State has adopted a Land Settlement Policy which, from a State viewpoint, followed what appeared at the time to be the line of least financial resistance. Hence, in this connection, State initial outlay has usually been limited to the laying down of railroads, parcelling out timber-clothed land into appropriate holdings, clearing roadways of scrub, and allotting land in virgin condition at low prices and on easy terms of repayment. Nor, unfortunately, has adequate provision for water always been made in advance. It follows, therefore, that the full burden of the reclamation of land from scrub, together with normal costs of settlement in new country, frequently fell upon settlers, the personal means of whom were unequal to the strain of early non-revenue producing years.

Nevertheless, it must be admitted that when the opening seasons of settlement proved unusually favorable, as was indeed the case in the settlement of the original Murray Mallee Hundreds, suitable settlers have been able to consolidate their financial position, notwithstanding apparent inadequacy of initial personal resources; but when the reverse has been the case, and opening seasons have been unfavorable, the majority of settlers have usually had to face one of two alternatives, namely:—

1. To take up an uneconomic burden of debt for an unknown number of years; or else
2. To abandon farms to newcomers, who, if more fortunate, would eventually reap the benefit of the labor of pioneers.

It is, however, too late in the day to speculate as to the probable course of events had a different policy of land settlement been adopted from the outset; and if under this heading I have referred to these matters at all, it is because the complete reclamation of Mallee Farms, and the vitally important association of Livestock operations with Wheat on these farms have been unduly delayed by our methods of Land Settlement in these districts. Recent events have thrown a flood of light upon the folly of limiting Farm Revenues to a single line of activity, notwithstanding its general adaptation to local conditions of climate and soil, and in more normal times to local economic conditions as well. Judicious Farming can perhaps best be described as a business, the main objective of which was to secure at a profit from a given area of land maximum mean pecuniary returns that soil, climatic conditions, available labor, and personal means admitted of; and, apart from exceptional circumstances, wheat growing as an exclusive source of farm revenue, cannot be said to comply satisfactorily with these requirements. For maximum mean returns, and perhaps indeed for mean profitable returns, in no part of the World can Wheat be grown to advantage when sown on the stubbles

of preceding crops; indeed, it is only in exceptional South Australian districts that wheat can be grown at continuous profit, even in alternative years only. Nor in any circumstances can exclusive wheat growing be said to offer continuous occupation to available home labor from one end of the year to the other. If, therefore, from the standpoint of South Australian farming generally, Wheat, to the exclusion of any other form of rural activity, can be said to be inadequate, this inadequacy is all the greater for the kind of farming typical of Mallee districts, which does not admit of the growing of wheat more frequently than once in three or four successive years.

In this connection the inadequacy of wheat alone in the Mallee may be illustrated from costing data of Mallee Farm No. 1.

In districts in which local conditions do not admit of wheat being grown more frequently than once in every three or four years on the same area of land, it is obvious that those farmers who limited their sources of revenue to Wheat alone must in each year have had from two-thirds to three-quarters of their arable land periodically out of crop. And, apart from a proportionate area treated as Bare Fallow over nine months of the year, or thereabouts, the only service this idle land could render to the farmer would be to reduce the amount of Hay and Oats usually consumed by Working Horses. In such circumstances it must be obvious, too, that Wheat grown on one-third or one-quarter of the arable area of the farm must carry the full burden of all Farm Yearly Overhead charges, such as Interest, Depreciation, Rates and Taxes, Value of Owner's Management and Personal Labor, General Expenses, &c. The Mean Value of these charges on Mallee Farm No. 1 has been as follows:—

	£	s.	d.
Interest on Land and Improvements	336	11	11
Interest on Working Capital (excluding Sheep)	137	0	5
Depreciation on Improvements and Plant	400	12	11
Rates and Taxes	29	18	3
Value of Owner's Management and Labor	300	0	0
General Expenses	114	6	1
Total Mean Overhead Yearly Charges	£1,318	9	7

Hence, if Wheat had been the exclusive source of Revenue of Mallee Farm No. 1, total mean overhead charges of £1,318 9s. 7d. would have to be borne by one-third of the total area—552 acres—if the land came under Wheat once in three years; and by one-fourth—414 acres—if the land came under Wheat once in four years. This would represent mean charges of £2 7s. 9d. per acre in the first instance, and of £3 3s. 8d. per acre in the second. On a bushel basis, for a mean crop of 16.92 Bushels, these charges would be respectively as follows:—

- 2s. 10d. per bushel for land under Wheat once in every three years; and
- 3s. 9d. per bushel for land under Wheat once in every four years.

In order to complete the comparison, the costs of Wheat grown every third and fourth year respectively have been calculated for a 16.92 bushel Harvest, and contrasted with the actually recorded costs of the mean of the three seasons under review, which illustrated the association of Wheat and Sheep.

Contrasting Costs of Growing Wheat as Exclusive Source of Revenue, with corresponding Costs of Wheat associated with Sheep: Mean Yield in each case is assumed to be 16.92 Bushels per Acre.

	Calculated Costs per Bushel of Wheat as Exclusive Source of Revenue.		Actual Costs per Bushel of Wheat in Association with Sheep.	
	Every 3rd Year.	Every 4th Year.		
	s. d.	s. d.	s.	d.
Interest on Land and Improvements	0 9	0 11	0	4
Interest on Working Capital	0 3	0 5	0	3
Depreciation on Improvements and Plant . .	0 10	1 2	0	8
Rates and Taxes	0 1	0 1	—	—
Labor and Management	0 8	0 10	0	6
General Expenses	0 3	0 4	0	3
Total Overhead Charges	2 10	3 9	2	0
All other Costs	0 11	0 11	0	11
	3 9	4 8	2	11

It will be noted that a 16.92 bushel crop of Wheat, when associated with a Flock of Sheep and such subsidiary crops as Sheep usually convert into profit, has been raised at a mean cost of 2s. 11d. per Bushel; and that, on the other hand, had Wheat been the exclusive source of revenue, a similar crop could not have been raised at less than 3s. 9d. per Bushel, with Wheat sown on the same land, once in every three years, and at not less than 4s. 8d. per Bushel with Wheat sown on the same land once in every four years. These figures should serve to stress a possibly unsuspected part which Live Stock operations play in the general economy of a Wheat Farm; they not only assist in maintaining the fertility of the land by replenishing dwindling stocks of Organic matter and checking undesirable Weed growth, but in addition offer under our conditions the immense economic advantage of reducing the costs of production of Main Crops, by assuming responsibility for a proportion of normal farm overhead charges, which would otherwise have to be borne in totality by these Main Crops.

Nor should it be forgotten that in skilful hands Live Stock Accounts can be made to close on Profit balances; but when associated with Wheat, or any other Main Crop, actual Net Profits, although desirable, are not absolutely essential to the technical success of Farm Live Stock Operations. Indeed, in such circumstances, Farm Live Stock Operations may be said to have technically succeeded on a Wheat Farm, when Revenue, plus Inventory Balances, do no more than equal inclusive expenditure. It has already been shown that on Mallee Farm No. 1 the association of Sheep with Wheat has had the effect of reducing the costs per Bushel of the latter by 10d. to 1s. 9d. per Bushel, according as Wheat is normally grown once in every three or once in every four years on the same area of land. These facts imply that apart altogether from the soil fertilising and weed destroying influences of the Flock, if the Sheep Account were to do no more than close on an even Balance, the mere presence of the Flock on the Farm would have had the effect of reducing Costs of Production of a Mean Crop of Wheat varying from 7,000 to 9,300 Bushels by £387 10s. to £612 10s. per annum. Finally, it can be added that even if the Sheep Account were to close on Debit Balances of £387 10s. or £612 10s., according to the length of the rotation in which Wheat was being grown, the general finances of the farm would be no worse off than if not a single head of Sheep had been kept on the farm, apart from slight increases in interest and depreciation charges on permanent improvements.

2. CONCERNING THE FARM FLOCK.

On the farm under review advantage has not hitherto been taken of Dairy Cattle, presumably because of the lack of adequate home Labor; and it follows that Live Stock Operations have not yet gone beyond the handling of a Flock of Sheep.

On the 1st April, 1929, when the Department of Agriculture first took over these Accounts, the Farm Flock consisted of 472 Sheep, comprising 2 Merino Rams, 4 Corriedale Rams, 100 Stud Merino Ewes, and 366 Flock Merino Ewes, valued in the aggregate at £822.

Before attempting to criticise on general lines the farm adequacy of a Flock of this type, it is necessary to stress the fact that the national interest in Live Stock operations is quite as great as that of farmers and graziers themselves; and in view of the magnitude of the issues involved, national economy must eventually refuse to admit any difference between these respective interests. The national concern in such matters is that there should be ample home supplies, coupled with a maximum surplus of readily exportable high-grade commodities; that is to say, from the standpoint of Sheep, an abundance of high-class Wool and of Lambs acceptable overseas at highest ruling rates. A Fat Lamb Flock that adequately complied with these national needs can be described as a Specialised Flock, eminently adapted to good average farm conditions, and which, in skilful hands, should eventually yield to the farmer maximum average returns that farm and season admit of. It is perhaps inevitable that over a vast tract of country embracing a wide range of climatic and soil conditions such as South Australia, variations in the character of the Flock or in its management should to some extent arise; nevertheless, these variations can be but slight when type or character of the Flock is concerned. From the latter standpoint a typical Fat Lamb Flock adequate to overseas requirements can be described as a Flock of half-bred Long Wool Ewes, namely:—Merino X Lincolns; Merino X Leicesters; Merino X Border-Leicesters; or Merino X Romney Marsh; but more generally of **large** framed, plain bodied Merino Ewes, mated in either case to Rams of one of the early-maturing Down Breeds, preferably South Downs or Suffolks. Probably of equal value as a Sire for Fat Lambs is the Ryeland, a sturdy, white-faced, short wool, early maturing British Breed, of which there are several Flocks in South Australia at the present time.

Under good management, Flocks of the above type, mated to suitable Rams, will produce Fat Lambs for which the highest rates would be paid on British markets, and upon which New Zealand's lamb Export trade has been successfully built up. Unfortunately, in Australia Fat Lambs have not yet been bred in numbers sufficient to give precedence to the export market, and to enable the latter to impose its standards upon the home market. In present circumstances, the home market usually absorbs not less than two-thirds of the lambs offering, leaving one-third only to the export trade. Moreover, the home Market, which is not too particular in the matter of type or quality, provided that the Lamb be prime enough, is able to outbid the export market at a time of the year when export Lambs would be likely to prove most profitable; hence, the average farmer, who is human, follows the line of least resistance, and with early but coarse Merino X Dorset Horn Lambs, or Merino X Shropshire Lambs, or even Merino X Leicester Lambs, caters for the market that offers quickest and highest returns, much to the detriment of export Supplies that invariably fall short in quality of New Zealand Lambs.

It is from the latter standpoint, namely, export quality in the Fat Lamb produced, that the original Flock of Mallee Farm No. 1 is most open to criticism. The Ewes, we have seen, were pure Merinos; nor, if of suitable type could any

exception be taken to them; but when one notes that 100 of these Ewes were described as Stud Ewes, and that 2 Merino Rams had been kept on the Farm, one realises that after all the Flock was only partly a Fat Lamb Flock. The 34 odd Merino Wether Lambs could no doubt be marketed locally, or even overseas, at 6½ to 7 months old, but at nothing like the profit that would have accrued had their place been taken by a corresponding number of well bred, well nurtured cross-bred lambs. The 44 Merino Ewe Lambs would continue in the Flock as Maiden Ewes for 2 to 3 years, and return slightly improved fleece values only. Hence, at best a small Merino Stud on a Farm can be described as an interesting hobby; but it cannot be recommended to the average farmer.

The balance of the Ewes were mated with Corriedale Rams, which from the Export Lamb standpoint must be described as quite unsuitable. There is no doubt that Corriedale Ewes when mated with Down Rams should drop high-grade Export Lambs, and prove excellent Dams for the purpose; but Corriedale Rams should be avoided as Sires if one has any regard for the national requirements of a uniform type of good quality Export Lamb. The owner of the Flock would appear to have realised the position, since in 1930 we find him introducing a Suffolk Ram to the Flock.

In the 1929-30 Season the number of Ewes sent to the Rams was 466, and the number of Lambs tailed 372, representing a Lambing percentage of 80, which from the standpoint of a small easily supervised Farm Flock, cannot be considered as more than moderately satisfactory.

In the 1930-31 Season the number of Ewes sent to the Rams was 351, of which 44, or 12½ per cent. were Maiden 2-tooth Merinos; the number of Lambs tailed was 301, or a Lambing percentage of over 85, which in the circumstances must be considered quite satisfactory.

In the 1931-32 Season 365 Ewes were sent to the Rams, and the number of Lambs tailed was 332, representing an excellent Lambing percentage of 91 per cent. The fact that Lambs were tailed between the 28th April and 26th November indicates that the Rams were allowed to run with the Ewes over the greater part of the year—an undesirable practice.

On the basis of twelve months' availability, the arable area of the farm was in each season distributed between Harvested Crops and Bare Fallow, on the one hand, and grazing on the other, as follows:—

	Areas on Basis of 12 Months' Availability.			
	1929-30.	1930-31.	1931-32.	1929-32 Means.
	Acres.	Acres.	Acres.	Acres.
Total Arable Area	1,655	1,655	1,655	1,655
Less Area of Harvested Crops and Bare Fallow	816	757	758	777
Area available for grazing	839	898	897	878

The area available for grazing can be subdivided as follows:—

	Areas on Basis of 12 Months' Availability.			
	1929-30.	1930-31.	1931-32.	1929-32 Means.
	Acres.	Acres.	Acres.	Acres.
Grazing Crops (Oats)	519	460	—	326
Cereal Stubbles	149	120	135	135
Land temporarily out of cultivation	171	318	762	417
	839	898	897	878

Although available grazing areas were in the main utilised by Sheep, to a minor extent both Horses and Cattle had access to them. The extent to which Live Stock other than Sheep has had access to these areas is shown in detail for each season in Table X of the Appendix, in which the grazing value of each area has been expressed in terms of equivalent sheep-days.

Table X shows in summary that the mean values of the grazing of various kinds of Live Stock during the three years were as follows:—

	Mean Values of Grazing. No. of Sheep Days. Per Annum.	Percentage. %
Sheep	143,460	85.2
Horses	13,800	8.2
Cattle	11,186	6.6
Totals	168,446	100.0

The mean Live Stock carrying capacity of the available grazing area for the three seasons was equivalent to not much more than one-half of a Sheep per acre per annum. This figure is extremely low, particularly when we take into consideration the fact that 37 per cent. of the available grazing area consisted of a relatively costly crop of Oats. The mean results show that of the three types of grazing available the Cereal Stubbles were the most efficient, namely, the equivalent of 0.70 Sheep per acre per annum; whereas a relatively costly Oat crop—0.53 Sheep per acre—was only slightly better than Natural Pasture—0.47 Sheep per acre. It should, however, be added that the Oat Crop was generally made to do something more than supply grazing for Sheep. In the 1930-31 Season, when the Oat Crop carried 0.49 Sheep per acre only, the 460 acres under Oats yielded as well 70 tons of Hay and 55 bushels of Oats, the feeding value of which would correspond to an additional 40,000 Sheep-days, which, if taken into account, would have raised the Sheep-carrying capacity of the Oat Crop from 0.49 Sheep per acre per annum to 0.73 Sheep per acre per annum. The latter figure is an improvement on the preceding one, but still too low to be worth while.

It should be stressed here, however, that relatively low Live Stock carrying capacity in the early years of Settlement is fairly characteristic of most Mallee areas, and that Mallee Farm No. 1 is by no means singular in this respect. Experience has already shown very definitely that not only in the Mallee, but over the greater proportion of South Australia's arable land, the residual effects of adequate phosphatic dressings applied to Cereal Crops had the effect of gradually building up the fertility of the land, which was always reflected in progressively improving Live Stock carrying capacity, whenever the land was temporarily left out of cultivation. From another point of view the great size of the paddocks that unavoidably characterises early years of settlement offers definite obstacles to effective grazing of what pasturage might be present. On a Farm of this character it is not at all unlikely that the grazing capacity of the land will be more than doubled in the course of the next ten years.

In addition to normal grazing indicated in Table X., Sheep have had occasional access to other portions of the Farm, as follows:—

	Equivalent No. of Sheep Days. 1929-32 Means.
Feeding off Wheat Crops	386.7
Feeding off Oat Crops	950.0
Grazing Early Fallow	7,511.6
Grazing Normal Fallow	23,394.0
Grazing on Neighbor's Farm	2,793.7
Total	35,036.0

Value of Extra grazing expressed as Sheep per acre

Hence, grazing availed of by Sheep over and above that supplied by normal areas may be taken to have been roughly equivalent to the grazing essential to the upkeep of 96 sheep over a twelvemonth.

The occasional grazing by Sheep of fallow land in the course of preparation for the succeeding year's Wheat Crop is not wholly for the benefit of the Sheep; indeed, from the latter point of view only, the value of the practice might well be questioned, since it invariably leads to the soiling of fleeces, and consequent reduction in their values per lb., and calls at times for a good deal of exercise for very little feed, and usually at the expense of the condition of the Sheep. From the standpoint of Wheat Crops, on the other hand, Fallow grazing presents several advantages, and since on a Wheat Farm wheat should normally take precedence of Sheep, the practice cannot be wholly condemned, provided that it be not overdone. The advantages to Wheat crops may be summarised as follows:—Grazing sheep tend to keep in check undue weed development on fallows, and tend to consolidate the loosely broken soil; hence, reduction in tillage costs, and therefore in general costs of Wheat production. Grazing Sheep, too, leave on the fallows new, easily broken down organic matter, coupled with Nitrogen in readily available form, both of which will be of use to future wheat crops. From another viewpoint, fallow grazing permits of the "spelling" of normal grazing areas, which are able to make new growth. Figures given above show that on Mallee Farm No. 1 Fallow grazing was roughly equivalent to one-quarter of a Sheep per acre per annum.

But as is the case on most farms, normal and occasional grazing areas did not suffice for the upkeep of the Flock from one end of the season to the other, and hand-feeding to some extent became necessary. As is usually the case, the need for hand-feeding became urgent when the stubbles had been exhausted, and before the new season's feed was available. This period—when the old season is on the decline, and before the new season has had time to open—is always a critical time for farms that carry Sheep; it coincides with Lambing time, too, when no Flock should be stinted of its food requirements.

In 1929 the Flock was supplied 264 bushels 8lbs. of Barley between the 1st of April and 29th of May, the value of which was £33 0s. 5d. In addition, £5 10s. was paid for grazing rights in a neighbor's property which, although not hand-feeding, is grouped with the latter as representing feeding costs incurred outside the farm. The costs are summarised below, with the aggregate expressed in terms of Ewes present on the farm on April 1st.

	£	s.	d.	
264.16bush. of Barley	33	0	5	
Outside Grazing	5	10	0	
Salt	0	10	0	
	£39	0	5	corresponding to 1s. 8d. per Ewe.

In 1930 hand-feeding took place between 27th of April and 28th of May, and included the following:—

	£	s.	d.	
1 ton Meggitt's Sheep Nuts	17	7	4	
6 tons of Hay	15	0	0	
153bush. Oats	19	2	6	
Salt	0	5	0	
	£51	14	10	corresponding to 2s. 11d. per Ewe.

In 1931 hand-feeding was very restricted, materials costing 7s. 6d. only. Losses from death in the three seasons were as follows:—

Seasons.	Losses from Death.			Total Losses.	Percentage of Flock.
	Size of Flock.	Ewes.	Lambs.		
	Nos.	Nos.	Nos.	Nos.	%
1929-30	472	34	1	35	7.4
1930-31	390	20	Nil	20	5.1
1931-32	422	17	15	32	7.6
Totals	—	71	16	87	—
Means per Season	428	24	5	29	6.8

It will be seen that in summary Mean Losses from death were 6.8 per cent. of the Flock per season; this percentage may be accepted as fairly normal.

3. OPENING AND CLOSING FLOCK INVENTORIES.

Details concerning Opening and Closing Flock Inventories are shown in the Appendix as Table XI. The salient features in these Inventories is the progressive decline in Sheep values per head, which were as follows:—

Mean Per Head Inventory Values of Sheep.

Inventory Dates.	Mean Values.	Progressive Declines per Head.			
		Relatively to Opening Inventory		Relatively to Inventory of Immediately Preceding Season.	
		Value.	Percentage.	Value.	Percentage.
	£ s. d.	s. d.	%	s. d.	%
1/4/29	1 14 10	—	—	—	—
31/3/30	0 17 9	17 1	49.0	—	—
31/3/31	0 12 3	22 7	64.8	5 6	31.0
31/3/32	0 11 7	23 3	66.7	0 8	5.4

Thus it will be seen that the per head value of the Flock had progressively declined between 1st April, 1929, and 31st March, 1932, to the extent of 23s. 3d. per head, or 66.7 per cent. Hence, in that interval of time the Flock lost two-thirds of its value, a fact which adequately accounts for the yearly losses incurred on the Flock. Had World Prices, and consequently Flock values, remained stationary, instead of declining, the Flock of Farm No. 1 would have been worth £600 in 1930, instead of £346, £632 in 1931, instead of £259, and £728 instead of £298 in 1932. From this source alone Flock losses aggregated £1,057 in three years, which should serve to stress the difficulties under which Sheep operations had labored of recent years.

4. FLOCK EXPENDITURE.

Details of Mean Flock Expenditure incurred in 1929-30, 1930-31, and 1931-32 Seasons have been summarised in Table XII. of the Appendix.

The details of the "Costs" given in this Table are in reference to a Mean Flock of 394 Ewes present on the farm at the beginning of the season, *i.e.*, 1st April. It should be added that additional Ewes were not purchased during the currency of the three Seasons. In the eighth column of the Table "Costs" have been reduced to a per-Ewe basis.

Reference to Table XII. will show how costly has been a Grazing Crop of Oats, namely, 8s. per Ewe, or 32.35 per cent. of total expenditure. Actually, however, the Cost per Ewe was greater than the figure shown in the Table, because an Oat crop was availed of in two seasons only, whereas 8s. per Ewe is the average

of three seasons, in one of which Oats were not grazed by Sheep. More correctly, the facts may be set out as follows:—

	s.	d.	
Cost of Grazing Crop of Oats in 1929/30	10	6	per Ewe
Cost of Grazing Crop of Oats in 1930/31	12	11½	per Ewe
No Oats grazed in 1931/32.			
Mean Costs of Grazing Oats in 1929/31	11	6½	per Ewe
Mean Costs of Grazing Oats in 1929/32	8	0	per Ewe

The costliness of the Oat Crop will be made clearer by comparing it with the Costs of Natural Pasture, *i.e.*, of arable land temporarily out of cultivation. In this connection the figures given in Table XII.—4s. 8½d.—cannot be used, because in Natural Pastures have been included both Stubble Grazing and Feeding-off of Crops and of Early Fallow. Mean costs incurred under the several headings during the three seasons may be summarised as follows:—

Cost of—	1929-32 Means.		
	£	s.	d.
Feeding-off Crops	0	15	11
Feeding-off Early Fallow	4	9	5
Grazing Stubbles	23	5	3
Natural Pasture	64	12	7
Totals	£93	3	2

Hence, the "costs" of grazing natural pasture by a Mean Flock of 394 Ewes were £64 12s. 7d., or 3s. 3½d. per Ewe, as against 8s. per Ewe for a grazing Crop of Oats, if we take three seasons into consideration, and 11s. 6½d. per Ewe if we take into consideration the only two seasons in which Oats were grazed. From another viewpoint it can be said that whereas the cost of one day's grazing of Natural Pasture is approximately 0.11d. per Sheep, representing agistment fees of ¼d. per week, the cost of one day's grazing of the Oat Crop was, roughly, 0.38d. per sheep, representing 2.66d. per week. Although the latter figure is clearly excessive, I am not prepared to argue that the farmer who keeps Sheep can afford to discard sown grazing crops altogether and trust to the spontaneous weed growth that may spring up upon land temporarily out of cultivation.

The costliness of the Oat crops we have had under consideration was due entirely to their low Sheep-carrying capacity, namely, not more than ½ Sheep per acre, instead of a minimum of 3 to 4 Sheep to the acre. The reason may have been unfavorable seasonal conditions, or possibly injudicious grazing; but, whatever the cause, Oats cannot be condemned as a grazing crop, even in the Mallee, on the bare results of these two unfortunate seasons.

The detailed expenditure set out in Table XII. has been summarised below in the alternative Statements A, B, and C, in contrast with Turretfield corresponding figures:—

Summarised Statements of Mean Expenditure per Ewe on Mallee Farm No. 1 (1929-32) in Contrast with Corresponding Turretfield Figures (1922-32).

STATEMENT "A."

From the Standpoint of Seasonal Operations.

	Mean Costs per Ewe.		Percentages.	
	Mallee Farm No. 1.	Turretfield.	Mallee Farm No. 1.	Turretfield.
	s. d.	s. d.	%	%
Tending Flock	3 7	4 8	14.6	18.4

Totals	24 8	25 7	100.0	100.0

STATEMENT "C."

From the Standpoint of Interest and Depreciation Charges.

	Mean Costs		In Terms of		In Terms of Ex-	
	Mallee	Turret-	"A" and "B",	clusive Expenditure.	Mallee	Turret-
	Farm No. 1.	field.	Mallee	Turret-	Farm No. 1.	field.
	s. d.	s. d.	%	%	%	%
Interest on Land and Im-						
provements	7 1	9 2	28.9	35.8	21.4	25.7
Interest on Floating Capital	1 6	1 5	6.0	5.5	4.4	4.0
Interest on Overdraft . . .	0 3	0 2	1.1	0.7	0.8	0.5
Depreciation of Improve-						
ments and Plant	2 9	1 6	11.0	5.9	8.2	4.2
Interest and Depreciation						
Charges	11 7	12 3	47.0	47.9	34.8	34.4
Balance of Expenditure . .	13 1	13 4	53.0	52.1	39.3	37.5
Gross Costs	24 8	25 7	100.0	100.0	74.1	71.9
Add Flock Depreciation . .	8 8	10 0	—	—	25.9	28.1
True Costs	33 4	35 7	—	—	100.0	100.0

These statements show that apart from Flock Depreciation, which will be considered later in conjunction with Flock Revenues, the mean "costs" of the Flock of Mallee Farm No. 1 were at the rate of 24s. 8d. per Ewe per annum. Mean costs at Turretfield were approximately similar, namely, 25s. 7d. per Ewe. In these "costs" grazing was represented by 12s. 9d. per Ewe, or 51.5 per cent. of total costs; hand-feeding by 1s. 10d., or 7.5 per cent., and tending Flock by 3s. 7d., or 14.6 per cent.

On the other hand, Labor was represented by 4s. 1d. per Ewe, or 16.4 per cent. of total costs and purchase of Materials other than Foodstuffs 3s. 9d., or 15.3 per cent.

Finally, Interest and Depreciation charges were represented by 11s. 7d. per Ewe, or 47 per cent. of total costs.

If Flock Depreciation be accepted as a "costing" item—and I see no valid reason why it should not—then the sum of 8s. 8d. per Ewe would have to be added to 24s. 8d., which would raise mean total costs to 33s. 4d. per Ewe. It has already been indicated that this heavy Flock Depreciation was in the main attributable to the unprecedented fall in prices which characterised these three seasons; it cannot therefore be accepted as normal.

5. MEAN FLOCK REVENUES.

Details of Flock Revenues in each of the three seasons, together with general means, are shown below in tabular form:—

Summarising Flock Revenues for 1929-30, 1930-31, and 1931-32 Seasons, together with Means of the Three Seasons.																	
	1929-30.				1930-31.				1931-32.				1929-32 Means.				Percentages.
	Total for 466 Ewes.		Per Ewe.		Total for 351 Ewes.		Per Ewe.		Total for 365 Ewes.		Per Ewe.		Total for 394 Ewes.		Per Ewe.		
	£	s. d.	s.	d.	£	s. d.	s.	d.	£	s. d.	s.	d.	£	s. d.	s.	d.

Gross Flock Revenue	533	19 0	22	11-00	309	2 8	17	7-37	253	14 0	13	10-82	365	11 10	18	6-70	100-0
+ or - Inventory Differences..	-476	2 6	-20	5-22	-94	12 6	-5	4-70	+31	15 8	+1	8-90	-179	13 1	-9	1-44	—
Net Revenue	57	16 6	2	5-78	214	10 2	12	2-67	285	9 8	15	7-72	185	18 9	9	5-26	—
Less Expenditure ...	592	7 1	25	5-08	572	16 3	32	7-67	294	15 7	16	1-83	486	12 11	24	8-44	—
Net Loss	534	10 7	22	11-30	358	6 1	20	5	9	5 11	0	6-11	300	14 2	15	3-18	—

The above data show that Mean Gross Revenue from the Flock was at the rate of 18s. 7d. per Ewe present on the Farm on the 1st of April. They also show that under the influence of the progressive fall in prices Revenue declined from year to year; they were 22s. 11d. per Ewe in 1929-30, 17s. 7d. in 1930-31, and 13s. 11d. only in 1931-32. If now we set side by side Gross Flock Revenue, Gross Expenditure, and Inventory Differences, we shall realise why on Mallee Farm No. 1 the Sheep Account closed on a Debit Balance in each successive season:—

Items per Ewe.	1929-30.		1930-31.		1931-32.	
	s.	d.	s.	d.	s.	d.
Gross Revenue	22	11.00	17	7.37	13	10.82
Less Gross Expenditure	25	5.08	32	7.67	16	1.83
	<hr/>		<hr/>		<hr/>	
	--	2 6.08	--	15 0.30	--	2 3.01
± Inventory Differences	--	20 5.22	--	5 4.70	+	1 8.90
	<hr/>		<hr/>		<hr/>	
Net Loss	--	22 11.30	--	20 5.00	--	0 6.11

From the above it will be seen that in each season Gross Expenditure, apart altogether from Flock Depreciation, exceeded Flock Revenue very appreciably—by 2s. 6d. per Ewe in 1929-30; by 15s. per Ewe in 1930-31; and by 2s. 3d. per Ewe in 1931-32. Praiseworthy attempts at economy were made in 1931-32, when expenditure per Ewe was reduced by 50 per cent., with the result that although Revenue per Ewe—13s. 11d.—was the lowest in the series, the difference between Revenue and Expenditure—2s. 3d. per Ewe—was also the lowest. The chief item of economy in this direction was omission to sow Oats for grazing purposes, probably because of the costliness of the practice in preceding seasons. Nor was Hand-feeding apparently necessary in 1931-32. The Inventory differences were negative in 1929-30 and 1930-31 because of continued fall in prices in these two seasons; but they were positive in 1931-32, when the position began to improve slightly. With a firm hand on expenditure, the owner should have no difficulty in converting the Losses of the three seasons under review into quite appreciable future profits.

D. TRACTOR FARMING COSTS.

1. *Introductory.*

Until the 1929-30 Season, field motive power had been supplied on Mallee Farm No. 1 partly by a team of 12 Horses and partly by a 12 h.p. Wheel Tractor. During the course of this season the owner decided upon a change of policy, involving the sale of his horses and Wheel tractor and the purchase of a more powerful Caterpillar Tractor. The new Tractor—a 20 h.p. Caterpillar—reached the Farm on November 11th, 1929. Nine of the horses were sold, and left the farm on November 26th, and the Wheel Tractor was discarded on December 2nd. It follows, therefore, that data collected in 1929-30 season were more or less incomplete from the standpoint of a normal season's work, and to that extent costing deductions derived therefrom are not wholly reliable.

2. *Performances of 12/16 h.p. Wheel Tractor.*

This tractor left the Farm on the 2nd of December; hence possibilities of work covered a period of 246 days from April 1st, 1929. Over this period it took part in the following operations:—

- (a) Combine-cultivating (16 tines) 225 acres of Fallow
- (b) Sowing with 16-tine Combine 89 acres of Oats
- (c) Sowing with 16-tine Combine 174 acres of Wheat
- (d) Driving Chaffcutter for 15½ tons of Hay.

Expenditure incurred on behalf of this Tractor over the period as follows:—

	£	s.	d.
Wages (exclusive of Field Labor)	4	12	4
Repairs	0	4	6
Sundries	0	11	5
Kerosene, Petrol, and Oil	32	11	2
Depreciation	34	7	8
Interest	7	18	4

Total Expenditure—April 1st to December 2nd . . £80 5 5

£80 5s. 5d. ÷ 182½ working hours = 8s. 9.56d. per Tractor-hour.

Thus, apart from Field Labor, but inclusive of Interest and Depreciation, the mean cost of one Tractor-Hour was about 8s. 9½d. It would be of interest to be able to determine the number of Horses that could be maintained at the same cost and on the same farm. Unfortunately, we have no data for a corresponding Mallee Farm, and are compelled to fall back upon the incomplete data of Mallee Farm No. 1, or upon the Mean 10-year data of Turretfield.

At Turretfield the mean cost of the Horse-hour (inclusive of Interest and Depreciation) was ascertained to be 4.67d. per hour. Such costs should normally be lower on a Mallee Farm; actually, however, owing to the incompleteness of the data, they were higher on Mallee Farm No. 1, namely, 5.18d. per Horse-hour. By dividing either figure—4.67d. or 5.18d.—into the known cost of the Wheel Tractor-hour—8s. 9½d.—we shall get the number of Horses that could be maintained for the same money, namely, 20.37 horses, if the incomplete data of Mallee Farm No. 1 be used, or 22.60 Horses if the Turretfield data be used.

Costs of the various operations in which this Wheel Tractor participated as Motive Power may be summarised as follows:—

A. Costs of Cultivating 225 Acres of Bare Fallow with 16-tine Combine.

Expenditure on 225 Acres.				Costs Per Acre.			
	Time.	Quantities.	Costs.		Time.	Quantities.	Costs.
	Hours.	Galls.	£ s. d.		Hours.	Galls.	s. d.
Field Wages	68	—	8 1 6		0.30	—	0 8.61
Use of Tractor	68	—	17 15 6		0.30	—	1 6.96
Use of Combine	68	—	4 8 1		0.30	—	0 4.70
Kerosene	—	130	11 4 5		—	0.58	0 11.97
Petrol	—	14	1 11 10		—	0.06	0 1.70
Oils	—	6	1 14 4		—	0.03	0 1.83
Totals			£44 15 8				3 11.77

From the above it will be noted that the costs of cultivating fallow with 16-tine Combine hauled by a 12/16 H.P. Wheel Tractor was a farthing less than 4s. per acre. In this aggregate the costs of the Tractor itself were about 1s. 7d. per acre, those of the Combine 4½d., those of motor spirit and oils 1s. 3½d., and field wages 8½d.

The work was carried out at the rate of 26½ acres per eight-hour day, involving a daily consumption of about 15.26 gallons of Kerosene, 1.65 gallons of petrol, and 0.71 gallons of lubricating oil.

Corresponding work with the same implement, hauled by ten horses, was carried out on 115 acres at the following costs:—

Expenditure on 115 Acres.			Costs per Acre.	
	Time.	Costs.	Time.	Costs.
	Hours.	£ s. d.	Hours.	s. d.
Field Wages	50	5 18 9	0.43	1 0.39
Use of Horses	500	10 15 10	4.35	1 10.52
Use of Combine	50	3 4 10	0.43	0 6.77
		£19 19 5		3 5.68

Hence, the work of hauling a 16-tine Combine Cultivator was done 6d. per acre cheaper when hauled by a ten-horse team than when hauled by a 12/16 Wheel Tractor. When hauled by a ten-horse team the cost of Wages plus the use of Combine—1s. 7.16d.—was greater than corresponding costs with Tractor haulage, namely, 1s. 1.13d. When, however, we compare the costs of the use of Horses—1s. 10.52d. per acre—with costs of the use of the Tractor plus combustion and lubricating oils, namely, 2s. 10.46d. per acre, we can realise the advantage that Horse has over Tractor power.

The 115 acres were cultivated in 50 hours, *i.e.*, in 6½ eight-hour days; hence, the area cultivated per day by the ten-horse team was 18.40 acres, against 26.47 acres by the Wheel Tractor. Speed of work, therefore, which in certain circumstances is of considerable importance, is the main advantage of the Tractor.

(b) *Combined Costs of Sowing with a 16-tine Combine 89 Acres of Oats and 174 Acres of Wheat.*

	Expenditure on 263 Acres.			Costs per Acre.		
	Time.	Quantities.	Costs.	Time.	Quantities.	Costs.
	Hours.	Galls.	£ s. d.	Hours.	Galls.	s. d.
Field Wages	98½	—	11 14 0	0.37	—	0 10.68
Use of Tractor	98½	—	25 15 0	0.37	—	1 11.50
Use of Combine-drill	98½	—	6 6 7	0.37	—	0 5.77
Kerosene	—	152	13 2 3	—	0.58	0 11.96
Petrol	—	17	1 18 9	—	0.06	0 1.77
Oils	—	6	1 14 5	—	0.02	0 1.57
			<u>£60 11 0</u>			<u>4 7.25</u>

Hence, mean costs of sowing Wheat or Oats with a Combine was 4s 7½d. per acre. In this aggregate the costs of Wages were 10½d. per acre, those of the use of the tractor 1s. 11½d., use of Combine 5½d., and fuel and oils 1s. 3½d.

The work was done at the rate of 21.36 acres per eight-hour day, during the course of which the daily consumption of Kerosene was at the mean rate of 12.5 gallons per acre, that of petrol 1.38 gallons, and that of oils 0.49 gallons.

Unfortunately, we have no comparative data of work done by the same implement hauled by Horses. The best comparison that can be offered is that of a ten-horse team hauling a 20-tine cultivator and sowing 58 acres of Oats. The data were as follows:—

	Expenditure on 58 Acres.		Costs per Acre.	
	Time.	Costs.	Time.	Costs.
	Hours.	£ s. d.	Hours.	s. d.
Field Wages	25	1 17 10	0.43	0 7.83
Use of Horses	250	5 7 11	4.31	1 10.33
Use of Combine	25	1 12 5	0.43	0 6.70
		<u>£8 18 2</u>		<u>3 0.86</u>

Hence, a ten-horse team hauling a 20-tine Cultivator sowed Oats at a cost of 3s. 0½d. per acre, whereas a Wheeled Tractor hauling a 16-tine Combine did similar work at a cost of 4s. 7½d. per acre. The Horse team did the work at the rate of 18.56 acres per eight-hour day, and the Tractor at the rate of 21.36 acres per day.

3. PERFORMANCE OF 20 H.P. CATERPILLAR TRACTOR.

This Tractor reached the farm on the 11th November, 1929, and was therefore present on the farm for 141 days of the 1929-30 Season. During this period the Tractor was at work for 399 hours, during the course of which the following expenditure was incurred.

1929-30 Tractor Expenditure for 399 Hours' Work.

	£	s.	d.
Wages (exclusive of Field Labor)	11	10	11
Repairs			
Sundries (Oil for Trial)	0	18	3
Kerosene (144galls.)	12	8	6
Petrol (548galls.)	62	8	6
Oils (42½galls.)	12	3	9
Depreciation	70	8	10
Interest	15	19	7
Total 1929-30 Expenditure	£185	18	4

£185 18s. 4d. for 399 hours = 9s. 3.83d. per Tractor-hour.

Expenditure incurred in 1930-31 for 1,148 hours of Work was as follows:—

	£	s.	d.
Wages (exclusive of Field Labor)	20	17	0
Repairs (Renewal of Parts)	8	8	8
Sundries (Overhaul)	0	17	3
Kerosene (1,683½galls.)	110	9	9
Petrol (711galls.)	76	11	4
Oil (102galls.)	24	18	9
Depreciation	138	18	0
Interest	37	2	8
Total 1930-31 Expenditure	£418	3	5

£418 3s. 5d. for 1,148 Hours = 7s. 3.42d. per Tractor-hour.

Expenditure incurred in 1931-32 for 1,005 hours was as follows:—

	£	s.	d.
Wages (Exclusive of Field Labor)	19	1	3
Repairs (Renewal of Parts)	4	16	3
Insurance	3	14	3
Kerosene (1,879galls.)	134	3	4
Petrol (205galls.)	24	7	8
Oil (79½galls.)	27	1	3
Depreciation	138	13	5
Interest	28	16	0
Total 1931-32 Expenditure	£380	13	5

£380 13s. 5d. for 1,005 Hours = 7s. 6.91d. per Tractor-hour.

Finally, Inclusive Expenditure of the 20 H.P. Caterpillar Tractor since 11th November, 1929, and 31st March, 1932, for 2,552 hours of work was as follows:—

	£	s.	d.
Wages (exclusive of Field Labor)	51	9	2
Repairs (Renewal of Parts)	13	4	11
Sundries	1	15	6
Insurance	3	14	3
Depreciation	348	0	3
Interest	81	18	3

Total Fixed Charges	£500	2	4	= 3s. 11.03d. per Tractor-hour
Kerosene (3,706½galls.)	£257	1	7	
Petrol (1,464galls.)	163	7	6	
Oil (223½galls.)	64	3	9	

Total Fuel and Oil Charges £484 12 10 = 3s. 9.58d. per Tractor-hour

Total cost of 2,552 hours £984 15 2 = 7s. 8.61d. per Tractor-hour

Finally, in Table XIII. of the Appendix a detailed statement has been given of work done by the 20 H.P. Caterpillar Tractor between the 11th November, 1929, and the 31st March, 1932.

The Mean Costs of the various operations are analysed below *seriatim*:—

(a) *Breaking Up 701 Acres with 8-Furrow Plough.*

	Time. Quantities.		Expenditure.		Per Acre.		Costs.	
	Hours.	Galls.	£	s. d.	Hours.	Galls.	s.	d.
Field Wages	502	—	54	0 11	0.72	—	1	6.50
Use of Tractor	402	—	73	13 10	0.57	—	2	1.23
Use of Plough	402	—	17	7 11	0.57	—	0	5.96
Kerosene	—	639	43	14 0	—	0.91	1	2.96
Petrol	—	222	24	1 7	—	0.31	0	8.24
Oils	—	34½	9	2 3	—	0.05	0	3.12
			£222	0 6			6	4.01

For portion of the time there was a man on the plough as well as a driver on the tractor. The work was done at the mean rate of 13.95 acres per 8-hour day, and absorbed 12.72 gallons of Kerosene per day, 4.42 gallons of Petrol, and 0.69 gallons of Oil. The mean cost was 6s. 4d. per acre.

Corresponding work by a team of ten horses on 316 acres was carried out at the following costs:—

	Time. Quantities.		Expenditure.		Per Acre.		Costs.	
	Hours.	Galls.	£	s. d.	Hours.	Galls.	s.	d.
Field Wages	281½	—	29	0 3	0.89	—	1	10.03
Use of Horses	2,815	—	60	15 2	8.91	—	3	10.15
Use of Plough	281½	—	12	13 5	0.89	—	0	9.62
			£102	8 10			6	5.80

The work was done at the rate of 8.98 acres per 8-hour day.

Hence, whilst a 20 H.P. Caterpillar Tractor broke up land with an 8-furrow plough at a cost of 6s. 4.01d. per acre, a ten-horse team did similar work at a cost of 6s. 5.8d. per acre; that is to say, assuming that the conditions under which the work was done were similar, the Tractor did the work at about 1½d. less than the 10-horse team. The Tractor in question is new, and whether it could continue doing the work at the same "costs" throughout its period of usefulness is, of course, another matter.

(b) *Breaking Up 309 Acres of Land with 14-Disc Sundercut Plough.*

	Time. Quantities.		Expenditure.		Per Acre.		Costs.	
	Hours.	Galls.	£	s. d.	Hours.	Galls.	s.	d.
Field Wages	220	—	16	14 2	0.71	—	1	0.98
Use of Tractor	110	—	21	7 0	0.36	—	1	4.58
Use of Plough	110	—	9	7 11	0.36	—	0	7.30
Kerosene	—	266	18	18 4	—	0.86	1	2.69
Petrol	—	22	2	12 4	—	0.07	0	2.03
Oils	—	9	3	1 6	—	0.03	0	2.39
			£72	1 3			4	7.97

The work was done at the mean rate of 22.47 acres per 8-hour day, and absorbed 19.34 gallons of Kerosene, 1.6 gallons of Petrol, and 0.65 gallons of Oil.

Similar work was done by a 10-horse team on 163 acres at the following costs:—

	Time. Quantities.		Expenditure.		Per Acre.		Costs.	
	Hours.	Galls.	£	s. d.	Hours.	Galls.	s.	d.
Field Wages	76	—	5	15 0	0.47	—	0	8.47
Use of Horses	760	—	16	8 1	4.66	—	2	0.15
Use of Plough	76	—	6	13 5	0.47	—	0	9.82
			£28	16 6			3	6.44

In the present instance, assuming work to have been done under similar conditions, the Horse-team work was 1s. 1½d. per acre cheaper than the tractor work, notwithstanding the fact that the tractor work was done at the rate of 22.47 acres per day, and the horse team work at the rate of 17.16 acres only.

(c) *Breaking Up 163 Acres of Grass Land with 16-tine Combine.*

	Time. Quantities. Expenditure.			Per Acre.		
	Hours.	Galls.	£ s. d.	Hours.	Galls.	Costs. s. d.
Field Wages	44½	—	5 5 8	0.27	—	0 7.78
Use of Tractor	44½	—	11 0 7	0.27	—	1 4.24
Use of Combine	44½	—	2 17 8	0.27	—	0 4.24
Kerosene	—	46	3 19 5	—	0.28	0 5.85
Petrol	—	53	6 0 9	—	0.33	0 8.89
Oils	—	4	1 3 0	—	0.02	0 1.69
Totals			£30 7 1			3 8.69

The work was done at the rate of 29.30 acres per 8-hour day.

We have no corresponding horse work data.

(d) *Cultivating 166 Acres of Fallowed Land with 14-Disc Sundercut.*

	Time. Quantities. Expenditure.			Per Acre.		
	Hours.	Galls.	£ s. d.	Hours.	Galls.	Costs. s. d.
Field Wages	52	—	6 13 10	0.31	—	0 9.68
Use of Tractor	52	—	9 6 11	0.31	—	1 1.51
Use of Plough	52	—	5 4 3	0.31	—	0 7.54
Kerosene	—	93	6 5 1	—	0.56	0 9.04
Petrol	—	20	2 3 2	—	9.12	0 3.12
Oils	—	5½	1 7 0	—	0.03	0 1.95
Totals			£31 0 3			3 8.84

The work was done at the rate of 25.54 acres per day, with a mean daily consumption of 14.31 gallons of Kerosene, 3.08 gallons of Petrol, and 0.85 gallons of Oil.

No work of this type was carried out with Horse-teams. It may be pointed out, however, that in the preceding section it was shown that to break up or plough land with a 14-Disc Sundercut hauled by a 10-horse team cost 3s. 6.44d. only; hence it is fairly certain that to cultivate fallowed land with the same implement would cost considerably less.

(e) *Cultivating 2,442 Acres with a 20-tine Combine.*

	Time. Quantities. Expenditure.			Per Acre.		
	Hours.	Galls.	£ s. d.	Hours.	Galls.	Costs. s. d.
Field Wages	575½	—	71 0 8	0.23	—	0 6.98
Use of Tractor	575½	—	109 3 11	0.23	—	0 10.73
Use of Combine	575½	—	25 1 2	0.23	—	0 2.46
Kerosene	—	1,161	78 10 2	—	0.48	0 7.72
Petrol	—	164	22 18 3	—	0.07	0 2.25
Oils	—	58½	16 15 6	—	0.02	0 1.65
			£323 9 8			2 7.79

The work was done at the mean rate of 33.96 acres per eight-hour day, with a mean daily consumption of 16.13 gallons of Kerosene, 2.28 gallons of Petrol, and 0.81 gallons of Oil.

Corresponding work on 372 acres by a ten-horse team hauling a 20-tine Combine was carried out at the following costs:—

	Time. Hours.	Expenditure. £ s. d.	Per Acre.	
			Time. Hours.	Costs. s. d.
Field Wages	118	12 4 9	0.32	0 7.90
Use of Horses	1,180	25 9 4	3.17	1 4.43
Use of Combine	118	7 7 0	0.32	0 4.74
		<hr/> £45 1 1 <hr/>		<hr/> 2 5.07 <hr/>

The work was done at the mean rate of 25.22 acres per eight-hour day, and at 2½d. per acre less than corresponding tractor costs.

(f) *Sowing Grain with 20-tine Combine (975 Acres).*

	Time. Quantities. Expenditure.			Per Acre.		
	Hours.	Galls.	£ s. d.	Hours.	Quantities. Galls.	Costs. s. d.
Field Wages	242	—	30 15 9	0.25	—	0 7.58
Use of Tractor . . .	242	—	45 9 11	0.25	—	0 11.20
Use of Combine . . .	242	—	9 18 9	0.25	—	0 2.45
Kerosene	—	274	19 9 7	—	0.28	0 4.79
Petrol	—	252	27 9 7	—	0.26	0 6.76
Oils	—	20½	6 1 7	—	0.02	0 1.50
			£139 5 2			2 10.28

The work was done at the mean rate of 32.23 acres per 8-hour day, with a mean daily consumption of 9.06 gallons of Kerosene, 8.33 gallons of Petrol, and 0.67 gallons of Oil.

Corresponding costs incurred on 339 acres by a 20-tine Combine hauled by a 10-horse team were as follows:—

	Time. Hours.	Expenditure. £ s. d.	Per Acre.	
			Time. Hours.	Costs. s. d.
Field Wages	139½	10 11 0	0.41	0 7.47
Use of Horses	1,390	30 0 0	4.10	1 9.24
Use of Combine	139	8 14 6	0.41	0 6.18
		<hr/> £49 5 6 <hr/>		<hr/> 2 10.89 <hr/>

The work was done at the mean rate of 22.79 acres per day, and at a cost of 0.61d. per acre more than tractor-work.

(g) *Sowing Grain with 20-Disc Drill (427 Acres).*

	Time. Quantities. Expenditure.			Per Acre.		Costs.
	Hours.	Galls.	£ s. d.	Hours.	Quantities. Galls.	
Field Wages	120½	—	15 5 3	0.28	—	0 8.58
Use of Tractor . . .	120½	—	23 11 4	0.28	—	1 1.25
Use of Drill	120½	—	14 13 10	0.28	—	0 8.26
Kerosene	—	157½	11 8 2	—	0.37	0 6.41
Petrol	—	56	6 1 5	—	0.13	0 3.41
Oils	—	10½	2 13 1	—	0.02	0 1.49
			£73 13 1			3 5.40

The work was carried out at the mean rate of 28.29 acres per 8-hour day, with a daily consumption of 10.43 gallons of Kerosene, 3.71 gallons of Petrol, and 0.70 gallons of Oil.

We have no horse-team data to compare with the above results.

(h) Harrowing 738 Acres of Land.

	Time. Quantities.			Expenditure.			Per Acre.			Costs.	
	Hours.	Galls.		£	s.	d.	Hours.	Galls.		s.	d.
Field Wages	110	—		9	11	0	0.15	—		0	3.11
Use of Tractor	82	—		15	16	0	0.11	—		0	5.14
Use of Harrows	82	—		10	18	8	0.11	—		0	3.55
Kerosene	—	162		11	9	2	—	0.22		0	3.73
Petrol	—	23		2	13	9	—	0.03		0	0.87
Oils	—	7½		2	10	3	—	0.01		0	0.82
				£52	18	10				1	5.22

The work was done at the mean rate of 72 acres per day, with a mean daily consumption of 15.80 gallons of Kerosene, 2.24 gallons of Petrol, and 0.73 gallons of Oil.

In these 738 acres were included 444 acres of land which were being harrowed immediately after ploughing. The work was done at the mean rate of 63.61 acres per day, and at a cost of 1s. 4.94d. per acre. The mean daily consumption of Kerosene was 15.54 gallons, of Petrol 1.85 gallons, and of Oils 0.92 gallons.

There were also included 210 acres of harrowing immediately after seeding. This work was done at the mean rate of 76.36 acres per day, and at a cost of 1s. 1.18d. per acre. The mean daily consumption of Kerosene was 16.36 gallons, of Petrol 2.84 gallons, and of Oils 0.36 gallons.

Costs of Harrowing 1,018 acres with a team of Horses were as follows:—

	Time.			Expenditure.			Per Acre.			Costs.	
	Hours.			£	s.	d.	Hours.			s.	d.
Field Wages	153½			13	16	9	0.15			0	3.26
Use of Horses	1,535			33	2	7	1.51			0	7.81
Use of Harrows	153½			6	6	7	0.15			0	1.49
				£53	5	11				1	0.56

The work was done at the rate of 52.97 acres per day, and at 4½d. less than corresponding Tractor-work.

(i) Reaping 1,343 Acres of Wheat with an 8ft. Header.

	Time. Quantities.			Expenditure.			Per Acre.			Costs.	
	Hours.	Galls.		£	s.	d.	Hours.	Galls.		s.	d.
Field Wages	704½	—		85	18	2	0.53	—		1	3.35
Use of Tractor	704½	—		146	2	6	0.53	—		2	2.11
Use of Header	704½	—		131	0	4	0.53	—		1	11.42
Kerosene	—	699		48	18	5	—	0.52		0	8.74
Petrol	—	490		55	12	11	—	0.36		0	9.95
Oils	—	57		16	16	0	—	0.04		0	3.00
				£484	8	4				7	2.57

The work was done at the mean rate of 15.25 acres per eight-hour day, with a mean daily consumption of 7.97 gallons of Kerosene, 5.56 gallons of Petrol, and 0.65 gallons of Oil. The mean cost per acre was 7s. 2½d., and as the mean yield per acre was 16.56 bushels, the mean cost per bushel was 5½d. The owner draws attention to the fact that these costs would have been lower but for the extremely tangled condition of half the 1930-31 Wheat Crops.

Unfortunately, we have no corresponding data for Horse-work.

(j) Reaping 165 Acres of Oats with an 8ft. Header.

	Time. Quantities. Expenditure.			Per Acre.			Costs.	
	Hours.	Galls.	£ s. d.	Hours.	Galls.	s. d.	s. d.	
Field Wages	89	—	10 17 4	0.54	—	1	3.81	
Use of Tractor	89	—	20 0 3	0.54	—	2	5.11	
Use of Header	89	—	15 13 3	0.54	—	1	10.78	
Kerosene	—	42	2 16 6	—	0.25	0	4.11	
Petrol	—	87	9 17 4	—	0.53	1	2.35	
Oils	—	11½	3 3 10	—	0.07	0	4.64	
Totals			£62 8 6			7	6.80	

The work was done at the mean rate of 14.83 acres per day, with a mean daily consumption of 3.77 gallons of Kerosene, 7.82 gallons of Petrol, and 1.03 gallons of Oils. The mean cost per acre was 7s. 6.80d., and for a 12.23 Bushel Crop the mean cost per Bushel was 7.43d.

Unfortunately, we have no corresponding data for Horse-work.

(k) Cutting and Binding 152 Acres of Cereal Hay with 8ft. Binder.

Totals			£45 12 7			6	0.05

Costs per ton (0.46 tons per acre) 13 0.44

The work was carried out at the mean rate of 22.52 acres per eight-hour day, at a cost of 6s. per acre, and 13s. 0½d. per ton for a crop averaging approximately half a ton per acre.

We have no corresponding data for Horse work.

(l) In Table XIV. of the Appendix the results of Tractor work and Horse-team work to the extent that the latter has been available have been summarised comparatively. It will be noted that there are six operations only in which outright comparisons were possible, namely, *one* between a 12/16 H.P. Wheel Tractor and a 10-horse team, and *five* between a 20 H.P. Caterpillar Tractor and a 10-horse team. These six operations and their relative costs are shown below:—

	Mean Costs per Acre.					
	Tractor.			10-horse Team.		
	£	s.	d.	£	s.	d.
1. Ploughing with 8-furrow Plough	0	6	4.01	0	6	5.80
2. Ploughing with 14-disc Sundercut	0	4	7.97	0	3	6.44
3. Cultivating with 16-tine Combine	0	3	11.77	0	3	5.68
4. Cultivating with 20-tine Combine	0	2	7.79	0	2	5.07
5. Harrowing (8 Leaves)	0	1	5.22	0	1	0.56
6. Sowing with 20-tine Combine	0	2	10.28	0	2	10.89
Totals	£1	1	11.04	0	19	10.44

Mean Tractor increased costs per acre 2s. 0.60d. total.
10.32 percentage.

Hence, for these six set of operations Increased Tractor Costs were represented by 2s. 0.60d., or 10.32 per cent. above corresponding Horse-Team Work. This may not seem much, but it must be recalled that Tractor costs given were those of a new tractor, and that they will certainly increase from year to year as the result of normal or accidental wear and tear of the machine.

An estimate based upon the above figures can of course be given as to the relative total costs of Tractor and Team work respectively in growing Wheat. Towards this end we shall adopt the mean Area under Wheat on Mallee Farm No. 1, namely, 422 Acres, for purposes of illustration. In this connection the only comparative costs of field operations that are not available to us are those that concern the reaping of the crop. For Tractor work the latter have already been shown to be at the mean rate of 7s. 2.57d. per acre. Hence, if we adopted the mean percentage increase of other operations, and assumed that Tractor Costs of reaping the crop were 10.32 per cent. higher than would have been corresponding costs of Horse-team work, then we should have 6s. 6.47d. per acre as estimated costs of reaping the Crop by means of Horse Team work. In the comparison, therefore, we shall assume that the fallows would have been broken at the mean rate of 5s. 5.99d. for the Tractor, and of 5s. 0.12d. for the Horse-team; that they would be cultivated three times at the mean rate of 3s. 3.78d. per operation for the tractor, and 2s. 11.3d. for the Horse-team; that they would be harrowed once at the mean rate of 1s. 5.22d. for the tractor, and of 1s. 0.56d. for the team of horses; that the seed would be sown at the mean rate of 2s. 10.28d. for the tractor, and of 2s. 10.89d. for the team of horses; and finally, that the grain would be reaped at the mean rate of 7s. 2.57d. by the tractor, and of 6s. 6.47d. by a team of horses.

In the circumstances, estimated costs of Field Operations in growing 422 acres of Wheat, but exclusive of overhead, costs of seed, etc., may be stated as follows:—

Estimated Costs of Field Operations in Growing 422 Acres of Wheat with Tractors and Horses as Motive Power Respectively.

	Estimated Expenditure.					
	With Tractor.			With 10-Horse Team.		
	£	s.	d.	£	s.	d.
Ploughing (once)	116	0	7	105	14	3
Cultivating (thrice)	209	16	9	186	12	0
Harrowing (once)	30	5	7	22	1	9
Sowing Seed	60	5	6	61	7	0
Reaping Grain	152	4	5	137	19	6
	<hr/>			<hr/>		
Totals	£568	12	10	£513	14	6
Tractor Excess	£54 18 4					

Hence, it is estimated that with a new Tractor in good working order, the costs of Field Operations in growing 422 acres of Wheat would be about £55, or 2s. 7½d. per acre, greater than corresponding costs of a 10-horse team. It is obvious, too, that the difference between Tractor Costs and Horse-team costs would become more pronounced with the progressive ageing of the tractor.

It must be recognised, however, that in the rapidity with which field operations can be carried out tractors present a very solid advantage over horses. The summarised data that follow will serve to make this point clear:—

	Number of 8-Hour Days Required to Complete 422 Acres.	
	Tractor.	10-Horse Team.
	Nos.	Nos.
Ploughing with 8-furrow Plough	30.25	46.99
Ploughing with 14-disc Sundercut	18.78	24.59
Cultivating with 16-tine Combine	15.94	22.93
Cultivating with 20-tine Combine (twice)	24.85	33.47
Harrowing (8 Leaves)	5.86	7.97
Sowing with 20-tine Combine	13.09	18.52
Totals	108.77	154.47

Aggregate saving in favor of Tractor-work . . 45.70 days.

Hence, for the operations indicated above, there would be an aggregate saving of 45½ days in favor of Tractor work; and on the grounds that "time is money" this represents a saving that cannot very well be overlooked. Not only are farm hands, tractors, and implements set free for other work, but in some instances Tractors render possible the carrying out of field operations at the most appropriate moment of the season. Seeding offers a simple illustration of this fact: It is generally recognised that ideal seeding weather is generally limited to a small number of days only in any given season, and it follows that in most instances portion only of the crop is sown at the most appropriate time, with the result that for no other cause crop yields may eventually be uneven, because portion of the crop had been sown too early, and portion of it too late. A saving of 5½ days in the sowing of 422 acres represents a saving of nearly 30 per cent. of the time required by a 10-horse team to do the same work. It should not be forgotten, however, that as the Tractor ages it becomes liable to breakdowns, and consequently to slowing down in the amount of work done in any given time.

Finally, it is claimed—and rightly so, perhaps—that tractors are responsible for reducing the Wages Bill on the farms on which they are used. The last two columns of Table XIV. of the Appendix show that such is the case for field operations of which we have dual records. The general position may be summarised as follows:—

	Mean Number of 8-Hour Labor Days Required for 422 Acres.	
	Tractor. Nos.	10-Horse Team. Nos.
Ploughing with 8-furrow Plough	37.77	47.01
Ploughing with 14-disc Sundercut	37.56	24.60
Cultivating with 16-tine Combine	15.95	22.91
Cultivating with 20-tine Combine (twice)	24.85	33.47
Harrowing (8 Leaves)	7.85	7.98
Sowing with 20-tine Combine	13.08	22.75
Totals	137.06	158.72

Number of Labor Days saved by Tractor 21.66

Hence, it is estimated that in the above operations the use of a Tractor has led to a reduction of Labor Wages in the costs of 422 acres of Wheat to the extent of 21.66 eight-hour days out of the 142 days required by horse-teams for corresponding work, *i.e.*, a reduction of 13.65 per cent. In this connection, however, it is necessary to stress the fact that from the viewpoint of neither the farmer nor the State is mere reduction in Labor Costs necessarily an unmixed blessing. Indeed, in no circumstances can such reduction be regarded as a desirable end in itself, but rather as a possibly unavoidable means to a desirable end, namely, reduction in mean costs of rural production; and in the matter before us there is no other end that can adequately justify the mechanisation of rural production. No other end, indeed, could possibly justify the progressive depopulation of our country-side, which usually accompanies extensive mechanisation. When, however, some special phase in the mechanisation of rural production—the use of Tractors, for instance—does lead to reduction in Labor Costs, but without corresponding decrease in costs of rural production, leads, in fact, to the very opposite effect, it must be obvious that this particular phase in mechanisation is neither in the interest of the farmer nor of the community as a whole. The importation of costly Machines and fuel from foreign parts, the over-capitalisation of our farms, coupled with progressively rising costs of rural production and gradual depopulation of the country-side, are not factors that make for the well-being and prosperity of an essentially rural State. It is on these grounds in the main that I have concluded that Farm Tractors have failed to justify their presence in our midst at a critical stage in our history.

E.—MEAN COSTS OF PREPARATION OF BARE FALLOW.

In the 1929-30 Season both Horses and Tractor participated in the preparation of Bare Fallow sown subsequently to Wheat in 1930-31. On the other hand, the motive power responsible for the 1930-31 and 1931-32 fallows was developed exclusively by a 20 H.P. Caterpillar Tractor. Hence, mean figures given below are confined to these two seasons. Unfortunately, data collected in the last season—which do not go beyond 31st March, 1932—are incomplete, as the fallows would in all probability receive a final cultivation just before seeding, at a cost estimated at £56 4s. 2d. for 464 acres. It follows, therefore, that data given in Table XV. of the Appendix under-estimate these costs to that extent. These data may be summarised as follows in contrast with corresponding data at Turretfield for the same two seasons:—

	Mallee Farm No. 1.			Turretfield.		
	Per	Per-		Per	Per-	
	Acre.	centage.		Acre.	centage.	
	s. d.	%		s. d.	%	
Wages	2 8	19.6		3 4	16.1	
Motive Power (Tractor or Horses)	7 5	53.6		7 0	33.9	
Use of Implements	0 9	5.3		1 10	8.9	
Rates and Taxes	0 3	1.9		0 8	3.2	
Interest on Land (Rent)	2 8	19.6		7 10	37.9	
Totals	13 9	100.0		20 8	100.0	

It will be observed that the discrepancy between the costs of Mallee Farm No. 1 and those of Turretfield is very considerable, namely, 13s. 9d. and 20s. 8d. respectively. An examination of the details, however, will show that the main causes of Turretfield excesses are Interest on Land values and rates and taxes, namely, in the aggregate 2s. 11d. per acre on Mallee Farm No. 1, and 8s. 6d. at Turretfield. If we deduct these two items from their respective totals we shall get 10s. 10d. and 12s. 2d., or a difference of 1s. 4d. per acre in favor of Mallee Farm No. 1, which possesses a soil far more easily tilled than that of Turretfield.

F.—VALUE AND DISTRIBUTION OF LABOR.

The available Arable Area of Mallee Farm No. 1 is 1,655 acres. The mean 1929-32 Area cultivated was 1,350.34 acres, the mean 1929-32 Area under Crop (including 343.67 acres of grazing crops) was 882.01 acres. If we relate Mean Wages paid per annum, namely, £394 17s. 6d. (inclusive of £300 for owner's salary) to mean eight-hour days worked, namely, 567½, we get the following results:—

Time and Cost of Labor per Acre in relation to—	Per Acre.	
	Time. Hours.	Costs. s. d.
Available Farm Area	2.75	4 9½
Mean Area in Cultivation	3.36	5 10½
Mean Area under Crop	5.15	8 11½

Attention is drawn to the fact that Mallee Farm No. 1 is a farm on which there is no available Home Labor, and that the owner, in addition to the burden of Management, is responsible for the greater portion of farm manual operations.

During the three seasons the Owner's working hours numbered 7,710½, i.e., a mean of 2,570 hours per annum, or an equivalent of 321 eight-hour days for payment at the assumed rate of 18s. 8d. per diem (£300 per annum).

Hired laborers, on the other hand, averaged 1,971 hours per annum, i.e., a mean of 246 eight-hour days per annum for payment at the rate of 7s. 8d. per diem, of which 4s. 8d. only represented payment in cash. The mean aggregate sum paid to Laborers per annum was £94 17s. 6d. In addition to the above a mean sum of £49 0s. 3d. per annum was paid for contracts.

Full details concerning the distribution of Wages (inclusive of Owner's Salary) have been given in Table XVI. of the Appendix. These data may be summarised as follows:—

Summarised Distribution of Wages Account (inclusive of Owner's Salary).

	Total.			Per Acre.			Per-centage.
	£	s.	d.	Arable.	Culti-vated.	Cropped.	
Crops (including grazing crops)	103	17	5	1 3	1 6½	2 4½	26.3
Fallows	58	11	6	0 8½	0 10½	1 4	14.8
Sheep	51	7	11	0 7½	0 9	1 2	13.0
Improvements	43	3	5	0 6½	0 7½	0 11½	10.9
Tools and Plant.	40	17	6	0 6	0 7½	0 11	10.4
Various.	96	19	9	1 2	1 5½	2 2½	24.6
Totals	£394	17	6	4 9½	5 10½	8 11½	100.0

Finally, details of Mean Contracts per annum were as follows:—

	£	s.	d.
1. Carting Wheat to Railway Station	23	16	1
2. Carting Superphosphate to Farm	4	2	8
3. Carting and Stacking Hay on Farm	4	1	8
4. Carting Wheat to Farm	1	13	2
5. Carting Kerosene and Petrol to Farm	1	4	6
6. Carting Wool and Lambs to Market	0	13	3
7. Carting Oats to Farm	0	12	6
8. Carting Stores to Farm	0	11	6
9. Carting Barley to Market.	0	8	4
10. Grading and Pickling Wheat	8	6	0
11. Dipping Sheep.	2	7	1
12. Sewing Bags	1	3	6
Mean Total per Annum	£49	0	3

In the above mean list, not all the items enumerated were represented in each year. Hence the following additional information concerning them is necessary:—

Mean of 2 years Contracts: Items Nos. 2, 4, 5, 6, 10 and 11.
 One year Contract only: Items Nos. 3, 7, 8, 9, and 12.
 Mean of 3 years Contracts: Item No. 1 only.

G.—COSTS OF SOME MINOR FARM OPERATIONS.

1. *Stooking Hay.*

An area of 181 acres yielded 100 tons of sheaved Hay, *i.e.*, about 11cwt. per acre. It took 78 hours, or 9½ eight-hour days' Labor. Mean Costs were therefore as follows:—

	Minutes.	Wages.
Costs per Acre	26	5.02d.
Costs per Ton	47	9.09d.

2. *Sewing Bags.*

(a) *Wheat.*—It took 473 hours, or 59 eight-hour days of Labor, to sew 7,333 bags of Wheat, at a cost of £31 13s. 4d. for Wages and £7 9s. 3d. for twine. Mean Costs would therefore be as follows:—

	Time.	Wages.	Twine.	Total Costs.
	Mins.	d.	d.	d.
Costs per Bag	3.87	1.04	0.24	1.28
Costs per Bushel	1.28	0.34	0.08	0.42

(b) *Oats.*—It took 49 hours, or six eight-hour Labor days, to sew 912 Bags of Oats, at a cost of £2 18s. 10d. for Wages and £1 16s. for Twine. Hence, Mean Costs were as follows:—

	Time.	Wages.	Twine.	Total Costs.
	Mins.	d.	d.	d.
Costs per Bag	3.22	0.77	0.47	1.24
Costs per Bushel	1.17	0.28	0.17	0.45

3. COSTS OF CHAFF-CUTTING.

It took 48 hours, or six eight-hour Labor Days, to cut 15½ tons of Hay, with a 12/16 H.P. Wheel Tractor for motive power. Similarly, it took 7½ hours to cut 5 tons of Hay with a 20 H.P. Caterpillar Tractor for motive power. In the latter case 2 tons of Hay were carted from the stack to the Chaff-cutter; in the former the hay was stacked alongside the Chaff-cutter.

Comparative costs are shown below:—

	12-16-h.p. Wheel Tractor (15½ Tons of Hay).			20-h.p. Caterpillar Tractor (5 Tons of Hay).		
	Total.	Per Ton.		Total.	Per Ton.	
	£	s.	d.	£	s.	d.
<i>Chaffcutting—</i>						
Wages	4	6	1	1	3	5
Tractor	3	9	10	1	4	10
Chaffcutter	3	1	9	1	0	0
Petrol	0	18	4	0	7	2
Kerosene	0	6	10	0	4	3
	£12	2	10	3	19	8
		15	8.00		15	11.2
<i>Carting to Cutter—</i>						
Wages				0	9	2
Horses				0	2	7
Trolly				0	3	4
				£4	14	9
					18	11.4

Thus, with a 12/16 H.P. Wheel Tractor providing the motive power, the cost of Chaff-cutting was 15s. 8d. per ton, and with a 20 H.P. Caterpillar tractor 15s. 11d. per ton; whereas inclusive cost of Carting and Cutting was 18s. 11½d. per ton with the Caterpillar Tractor. All these costs are obviously too high, probably because both Tractors were too powerful for the work required of them, and in the end too costly. At Turretfield, Carting and Cutting with a stationary engine providing the motive power to drive the chaffcutter, corresponding costs were 13s. 4.2d. per ton only, compared with 18s. 11.4d.

CONCLUSION.

The Report on three seasons' Farming Operations of Mallee Farm No. 1 has now been brought to a close; and, viewing the position in retrospect, it can be said that the variations in seasonal climatic conditions, and, in our experience, in economic conditions as well, are usually too great to yield convincing means from the results of three brief years of farming operations. If it had been possible to join the data of Mallee Farm No. 1 to those of two other farms situated in the same district the resulting means would, in all probability, have been more satisfactory; and it was because such farms were not available at the time that we sought to induce the Owner to allow us to continue the analysis of his data for an additional two years. Unfortunately, he was unable to agree. We are none the less grateful to him, not only for placing at our disposal all the data of his farm, but for the painstaking and conscientious manner in which all the records required by us were personally kept by him; and for this and for his many kindnesses to Departmental Officers we wish to tender to him our sincere thanks, and to express the hope that our brief association will result in some good to himself, as it will to ourselves.

I must also express my personal indebtedness to the Accountant (Mr. J. W. McDonald) and his Staff for the workmanlike manner in which the numerous data

upon which this Report has been founded have been collected and brought together. I am particularly indebted to Mr. H. S. Soar (Assistant Accountant) who was mainly responsible for the successful handling of these data during three successive years.

Let me say, in conclusion, that although circumstances did not permit of the work being continued on Mallee Farm No. 1, we have other farms in hand concerning which Reports will be published in due course.

APPENDIX.

NOTE.—It is estimated that to complete preparation of 1931/32 fallows a sum of £56 4s. 2d. would have to be spent; this additional expenditure would raise the total cost of preparing 1,005 acres of bare fallow to £746 18s. 8d., or 14s. 10d. per acre; corresponding costs at Turrethfield, where land values are higher and soil heavier, were 26s. 1d. per acre for the 10-year period ending March 31st, 1932. Costs were, however, very considerably reduced in the last two years of the decade, namely, 20s. 8d. per acre for the preparation of 1930/32 bare fallow.

THE ESTABLISHMENT AND MANAGEMENT OF IRRIGATED PASTURES.

[By H. C. TRUMBLE, M. Agr. Sc., Waite Agricultural Research Institute.]

Under the conditions of the irrigated Murray swamps it is possible to grow four types of forage:—(a) Summer and winter-crown cereals; (b) temporary pasture for grazing or for cutting and feeding to stock; (c) lucerne for permanent mowing; and (d) permanent seeded pastures. Permanent seeded pastures are particularly desirable owing to their known high productivity under irrigation and their ability to produce feed at low cost when once they are established.

BASIC IMPORTANCE OF NITROGEN AND PHOSPHORUS IN PLANT GROWTH AND ANIMAL PRODUCTION.

On considering the factors that govern the yield and productivity of pastures in general, it is necessary that we should fully understand the importance of the elementary food materials, particularly nitrogen and phosphorus, in determining the yield and nutritive value of pastures and the health and production of livestock.

Nitrogen is a gas which forms four-fifths of the atmosphere we breathe, but as such is useless both to plants and to animals. It can be used by certain soil bacteria, however, which convert it into nitrates and ammonium compounds which in turn can be taken up by plants which convert them into proteins. Proteins are the essential constituents of meat and wool, and are also important constituents of milk. A low protein content of herbage is frequently a cause of poor nutrition and low productivity of stock.

Phosphorus on the other hand is a solid which is found in the soil as phosphate. The soil cannot be enriched in phosphate except by the addition of phosphatic fertilisers such as superphosphate. Phosphates are chiefly found in bony structures, but are also essential constituents of nearly all animal products. The importance of both nitrogen and phosphorus can be gauged from the fact that they are necessary constituents of all plant and animal cells.

REQUIREMENTS OF GRASSES AND CLOVERS FOR NITROGEN AND PHOSPHORUS.

It is important to know that whereas grasses require both nitrogen and phosphorus in fairly liberal quantities for growth, clovers, lucerne, and other leguminous plants are able to obtain all the nitrogen they require from the air by means of bacteria which inhabit small nodules found on the roots of these plants. It is found in practice that grasses respond more readily to nitrogenous manures than clovers, whereas clovers respond actively to soluble phosphates and are actually depressed by nitrogenous fertilisers such as sulphate of ammonia. This is connected with the fact that both grasses and clovers require three to four times as much nitrogen as they do phosphate, whereas the clovers are independent of the soil nitrogen. This characteristic of the clovers is of paramount importance in pastures, for clovers actually enrich the soil in nitrogen and improve the growth of grasses growing in association with them.

AMOUNTS OF NITROGEN AND PHOSPHORUS REQUIRED BY PASTURES.

The amounts of nitrogen and phosphoric acid required by a year's growth of pastures are considerable. Investigations at Wood's Point have shown that 680lbs. of nitrogen and 210lbs. of phosphoric acid equivalent to 30cwts. sulphate

View of experimental area at Wood's Point showing plots grazed rotationally by sheep, with protected quadrats from which the yield of pasture is obtained.

of ammonia and 9cwt. of superphosphate per acre respectively are removed from the soil in a year's growth of herbage. Only about 50 per cent. of these quantities is returned and retained by the soil, so that there is a continual drain on the soil supply of these two nutrients; consequently, an annual application of soluble phosphate is necessary to keep pace with the loss of phosphorus. In the case of nitrogen the loss is greatly compensated by the nitrogen-fixing capacity of the clovers.

WELL-BALANCED MIXTURES OF GRASS AND CLOVER NECESSARY.

It is obvious that neither pure grass swards nor pure clover swards are desirable as pastures. The pure grass sward soon becomes unproductive owing to the using up of the available soil nitrogen without any compensating replacement; whereas the pure clover sward is too rich and unbalanced a food for stock. Moreover, its high nitrogen-fixing propensity leads to a condition of nitrogen excess, which causes the clover to deteriorate and inferior grasses and weeds to take possession of the soil. Lucerne is an exception to this rule when it is mown because most of the nitrogen is removed in the carted forage. When lucerne is grazed it behaves in a similar fashion to the clovers.

It is thus necessary to establish well-balanced mixtures of permanent grasses and clovers in which the clovers act as gatherers of nitrogen and the grasses make use of this nitrogen, yielding it to stock, the grasses and clovers together providing a balanced ration containing protein and phosphoric acid in suitable proportions and amounts for the requirements of grazing livestock.

A large number of grasses, clovers, and mixtures has been tested by the Waite Research Institute on the Wood's Point Estate during the last 3½ years. Relatively few of these have been found sufficiently productive, particularly in winter, and persistent enough under grazing to justify their being recommended for permanent pastures.

SUGGESTED SEEDS MIXTURES.

Certified New Zealand perennial rye grass has proved the outstanding permanent grass and certified New Zealand white clover the outstanding clover. The mixture recommended is 10lbs. certified perennial rye grass, 8lbs. Akaroa cocksfoot, and 2lbs. certified white clover. It is possible that the Montgomery type of red clover may be available in the future, in which case the addition of 2lbs. per acre to the above mixture is recommended.

A grass which has given promising results in many parts of the State, including the swamps, is *Phalaris tuberosa*, a species particularly valuable for its winter growth. Unfortunately, this grass does not grow well in association with perennial rye grass. A suitable mixture containing this species is 4lbs. *Phalaris tuberosa*, 4lbs. Kentucky blue grass, 2lbs. certified white clover, and (when available) 2lbs. Montgomery red clover.

ESTABLISHMENT OF THE PASTURE.

It is always necessary to purchase good seed, and certified lines of perennial rye grass, white clover, and *Phalaris tuberosa* are now available at fairly reasonable prices.

Sowing down after a lucerne stand which has commenced to thin or has been destroyed by flooding gives good results. It is not recommended to plough good lucerne in a state of high productivity unless this cannot be avoided. Good soil preparation is essential.

Seeding in late winter or early spring—August to early September—has given good results, but seeding may be carried out in autumn if winter weeds are not troublesome. In the case of a *Phalaris* mixture autumn seeding is preferable. The seeds are usually sown by mixing thoroughly with superphosphate and allowing to drop on a well tilled surface, then lightly harrowing.

MANAGEMENT.

Subdivision of paddocks to sizes of from 5 to 10 acres is desirable, as without this it is extremely difficult to exercise grazing control.

The pasture should be lightly grazed 10 to 12 weeks after seeding, then at intervals of 5 to 6 weeks. It has been found in practice that even and thorough grazing is desirable and can usually only be attained by putting on comparatively

Close view of pasture sown with New Zealand certified perennial rye-grass, cocksfoot, and white clover, with quadrat removed to show growth of pasture.

large numbers of stock for short periods of time, which means fairly frequent rotation. Five or six paddocks with the stock in each paddock for a week at a time would give a satisfactory grazing interval. Ideally, the grazing should not be sufficiently drastic to bare down the pasture and expose a large proportion of bare soil. If possible, a short cover of grass an inch or two in height should be maintained.

View of sheep grazing on 150 acres of New Zealand certified perennial rye grass, cocksfoot, and white clover at Wood's Point.

In Great Britain and in New Zealand the grazing interval recommended has been one of 3½-4 weeks. Wood's Point experience indicates, however, that an interval of 5-6 weeks is more suited to the conditions of the swamps. A system of 8-weekly cutting produced 31 per cent. more herbage over a 12 months' period than 4-weekly cutting, and also provided a more suitable ration for fattening sheep.

IRREGULARITIES OF SEASONAL PRODUCTION.

The production of herbage shows wide fluctuations both in yield and nutritive value according to the period of the year. Approximately 25 per cent. of the total annual production is yielded in the two months, October and November, whereas only 15 per cent. is produced in the four months, June, July, August, and September. On the other hand, the herbage in winter is 40 per cent. richer in phosphorus and 30 per cent. richer in nitrogen than it is in summer. Supplementary feeding in winter should thus take the form of a carbohydrate supplement, such as cereal hay or barley grain.

It is very important that the herbage should not be allowed to get away in spring in the case of irrigated pastures. The reverse is true for non-irrigated sown pastures where spelling in spring is frequently desirable. Under irrigation, however, a heavy yield in October and November followed by close grazing or cutting appears to lead to poor production subsequently. To avoid this, either the grazing interval can be shortened and more stock used to graze the pasture, or, failing this, the pasture should be mown at an early stage of growth.

It is advisable either to graze or to mow, if at all possible, before the grasses actively commence to flower.

MANURING.

An application of superphosphate at the rate of 1½cwts. to 2cwts. per acre is desirable each year. Little response to superphosphate has been obtained at Wood's Point, but this is probably because the land has received liberal dressings of superphosphate in past years.

Sulphate of ammonia is not profitable on irrigated pastures at present prices, but may be used where a rapid stimulation of feed production is required for special purposes.

PASTURE RENOVATION, HARROWING, MOWING, ETC.

Pasture renovation does not appear to be necessary on the Murray swamps with rye grass pastures. Harrowing is, however, advisable in order to distribute cow pats. The use of the mower is beneficial where irregularities, roughness, and thistles appear or where selective grazing has been evident.

A good variety in the feed is very desirable, and it is suggested that more than one pasture mixture should be sown. It might be useful, for instance, to have pastures of both rye grass and of *Phalaris* on a block rather than to sow rye grass mixtures exclusively. For permanent mowing lucerne is unequalled, whereas temporary leys of Italian rye grass, 10lbs. per acre and broad red clover 5lbs. per acre, may be sown for the rapid provision of greenfeed.

In conclusion, fodder conservation in the form of cereal hay and grain, lucerne hay, and stacked silage greatly augments and stabilises production and acts as a safeguard against lean periods.

INVESTIGATION DESIGNED TO IMPROVE CULTURAL PRACTICES IN THE CURRANT-GROWING INDUSTRY IN NON-IRRIGATED DISTRICTS OF SOUTH AUSTRALIA.

[Mr. G. Quinn (Chief Horticultural Instructor) has presented the following report for the information of the Hon. Minister of Agriculture and the Dried Fruits Board. The report covers the first year's operations conducted by the officers of the Horticultural Branch in collaboration with officers of the Council for Scientific and Industrial Research in vineyards in the currant-growing districts around Clare, Barossa, and McLaren Flat.]

The investigation is at present directed towards:—

- (1) Methods of re-organising old debilitated vines in low yielding and unprofitable vineyards.
- (2) Testing the comparative values of various systems of pruning in relation to the productivity of currant vines.
- (3) Testing crop-yielding capacities of normal currant vines preparatory to instituting manurial trials.
- (4) General bud shoot, bunch and berry growth studies on vines under No. (2) treatments.

In each of the above districts three plots of currant vines were selected in vineyards which had been offered by the respective owners for the purposes of the investigation—as stated above and outlined in detail in a previous explanatory report dated September 3rd, 1932.

(1) METHODS OF RE-ORGANISATION OF OLD VINES.

In Mrs. A. Dolan's very old vineyard on the rich Stanley Flat near Clare, two rows consisting of 121 vines were sawn off practically at ground level, but usually at a point where water shoots had started or were giving signs of emergence. The owner had removed the old trellis and erected a new one about 5ft. high on which to train the new growths. To this the available water sprouts were raised or directed by suitably placed stakes and ties, and fixed in position during the pre-bud bursting period in 1932.

It has been planned to raise each alternate vine to the top wire and frame it there, whilst the others will be spread espalier shape on the middle wire. Where no water sprout was available on any stump, the young growths which emerged in spring were led up by a supporting string—around which they were temporarily twisted—to the trellis wires, and there topped to induce subdivisinal growths from which the permanent horizontal arms are being formed.

The number of old vines which responded with healthy shoots was 112, or equivalent to 92.5 per cent. of the total operated upon in the two rows.

With a view to making comparisons, the owner cut off a third row, each alternate vine being severed about 9in. or 10in. above ground level where water shoots have or may emerge.

In all of these amputations the wounds on the stumps were smoothened over and carefully coated with thick white lead paint to prevent the ready entrance of decay-producing organisms.

With a view to arriving at an estimation of the loss of fruit likely to be sustained during the re-organisation period, two of the owners have, on our suggestion, gathered and weighed the currants harvested from an equal number of

rows of the old vines immediately adjacent to those decapitated. This procedure will be followed until the re-organised vines have gradually reached a normal cropping condition. In Mrs. Dolan's the owner reported that three rows comprising 173 old vines planted 10ft. x 11ft. yielded 4,059lbs. of fresh fruit, resulting in 1,424lbs. of dried currants—a drying ratio of 2.85lbs. fresh to 1lb. dried weight. The growths arising from the re-organised vines have been satisfactory, and cropping will no doubt begin on some of the stronger plants during the coming summer if permitted.

In Mr. G. Wishart's 60-year-old vineyard at Angaston three rows consisting of 124 vines planted 8ft. 6in. apart, with vines varying from 8ft. to 16ft. apart in the rows, were cut off and treated in a similar manner to those at Mrs. Dolan's. These vines were of the Shiraz variety for 40 years before being grafted over to currants. The response in growth following our amputations was very remarkable—116 or 93.54 per cent. of the vines produced canes enabling reconstruction to be entered upon during the first summer. A new trellis was also erected by Mr. Wishart to accommodate these growths.

The fresh currants harvested in 1933 from the next adjacent three rows of old vines weighed 1,407½lbs., whilst the few more advanced growths on the reconstructed vines carried 10½lbs. of grapes.

In the 30-year old vineyard of Mr. R. G. Bell of McLaren Flat two rows consisting of 78 vines were cut off in a similar manner to those at Stanley Flat and Angaston, and the resulting growths tied to a new trellis erected to receive them. Of the vines operated upon 76 have grown, equalling 97.43 per cent. of the total.

In this instance, owing to an oversight, no arrangement had been made with the owner to keep a record of the crop gathered from an equal number of old adjacent vines in the same plot.

(2) TESTING THE COMPARATIVE VALUES OF DIFFERENT SYSTEMS OF PRUNING IN RELATION TO THE PRODUCTIVITY OF CURRANT VINES.

In Mr. W. H. Penna's well kept 20-year-old vineyard at Sevenhills, near Clare, 99 vines, comprising two full rows and portion of a third row, were selected for these trials. The outside vine at each end of the rows was omitted. These 99 vines had, at pruning time, been marked off into groups, each containing three consecutive vines as they stood in the rows. These vines, which are planted in rows 10ft. apart with the plants set 11ft. from each other in the rows—396 vines to an acre—are trained as espaliers, each having one pair of arms. The rows run approximately north and south along the gently sloping land. The vines were consecutively numbered from 1 to 99 from north to south along the respective rows.

In each of the groups one vine labelled "S." was spur pruned. The next one marked "S.D." was also spur pruned, but after bud burst all sprouts not arising from the spurs were disbudded, *i.e.*, quite suppressed. The third vine, labelled "R.S.", was rod and spur pruned. This order was repeated along the rows, making 33 groups or replications of each of these treatments.

The fruit was harvested on March 22nd, when the Baume scale recorded from 12.75° in the fruit from the rod and spur pruned vines to 15.50° in that from the spur pruned and disbudded vines.

The harvesting procedure adopted was to first harvest the fruit from the rods on the rod and spur pruned vines and record the weight of its grapes to each particular vine. The remaining grapes from each vine in all of the groups were then harvested, and the bucket or buckets containing same were stood against the stem of the vine from which their contents had been picked. The weighing and recording officers meanwhile followed closely on the heels of the pickers, and collected the data from each vine's yield before the buckets were passed to the

carters for delivery to the drying ground where the fruit gathered from the spur pruned, spur pruned and disbudded, the rods from the rod and spur pruned vines and from the spurs on the rod and spur pruned vines were each spread on separate lots of trays for drying.

NOTE.—Owing to the grapes from four groups having been mixed on the drying trays, the data has been drawn from 29 groups only.

The production from the variously pruned groups may be summarised as under:—

Method of Pruning.	No. of Vines.	Total Yield.	Average per Vine.	Degrees Baume.	Total Dry Weight.	Drying Ratio.	Total Yield per Acre Rate Fresh Grapes (at 396 Vines per Acre).
S. (spur pruned)	29	lbs. 789½	lbs. 27.22	13.75	lbs. 257¼	3.07 to 1	Tons cwt. 4 16¼
S.D. (spur pruned and disbudded)	29	673	23.20	15.50	220¼	3.05 to 1	4 2
R.S. (rod and spur pruned)							
Rods	29	494½	17.05	12.75	153½	3.22 to 1	} 6 2¼
Spurs		508½	17.53	12.75	156	3.26 to 1	

The fruits when dried were processed and classified into commercial grades at the Clare Dried Fruits Association's Co-operative Shed, which kindly consented to undertake this phase of the investigational work.

At Mr. P. B. Boehm's 9-year-old currant vineyard at Light's Pass, near Angaston, a similar number of vines—viz., 99—to those selected at Mr. Penna's, at Sevenhills, have been subjected to the pruning treatments outlined above. These vines are planted in rows 10ft. apart with plants set 12ft. from each other in the rows, making a total of 363 vines per acre planted. They are framed as spaliers, each vine carrying one pair of arms stretched on a low trellis, and the 33 groups occupy five and one-half rows running approximately east and west. The tips of the young shoots were slightly injured by frost in early spring, but apparently the yield was not seriously diminished thereby.

The crop was harvested and the weights recorded on March 14th, when the Baume readings indicated from 13.57° from the juices of fruits on the rods, to 14.76° on the spur pruned, but not disbudded vines. The following is a summary of the yields at Light's Pass:—

Method of Pruning.	No. of Vines.	Total Yield.	Average per Vine.	Degrees Baume.	Total Yield Dried.	Drying Ratio.	Yield per Acre Rate Fresh Grapes.		
		lbs.	lbs.		lbs.	lbs.	T.	C.	L.
S. (spur pruned)	33	563½	17.08	14.76	171	3.29 to 1	2	15	41
S.D. (spur pruned, disbudded)	33	540½	16.38	14.50	163	3.31 to 1	2	13	9
R.S. (rod and spur pruned)	33								
Rods		298	9.29	13.57	85	3.50 to 1	3	9	82
Spurs		412	12.48	13.76	98	4.20 to 1			

These yields have been dried separately, and the drying ratios, grades of commercial quality, bucks, and waste obtained through the kindly co-operation of the Co-operative Packing Association's shed at Angaston.

The following figures indicate in tabular form the results of the final processing and grading of the dried produce:—

The pruning test plot on Mr. R. G. Bell's 13-year-old currant vineyard at McLaren Flat consisted of three rows of moderately strong vines trained as simple spaliers on a well set up trellis. The rows, which run down a gentle slope in a northerly aspect, are 10ft. apart, and the vines are placed 10ft. from each other in the rows, or equalling 435 vines on an acre surface.

The vines were pruned in groups of three as in the Sevenhills and Light's Pass tests. Each treatment was thus replicated 42 times on a total of 126 vines. An average of four rods were left on each vine in the R.S.—rod and spur—pruned plants.

The harvesting of the fruit was carried out on March 14th. The fruit was dried by Mr. Bell in a dehydrator on the property. The following is a summary of the yields from the different treatments at McLaren Flat:—

Method of Pruning.	No. of Vines.	Total Yield.	Average per Vine.	Degrees Baume.	Total Dried.	Drying Ratio.	Yield per Acre Rate Fresh Grapes.		
		lbs.	lbs. ozs.		lbs.	lbs.	T.	C.	L.

Spurs					86.88%		

Owing to a misunderstanding the data collected from this processed fruit was not recorded on a similar scale to that of the dried fruit from the Sevenhills and Light's Pass Pruning plots, where it was graded out in detail and classified on the standards adopted by the Australian Dried Fruits Association for currants.

(3) CROP YIELD TESTS.

These tests were carried out in portions of vineyards wherein the vines were said to have displayed normal average growth and fruit production under the soil conditions predominating in the currant vineyards of each respective district during recent years.

In the Clare district this plot is contained in the vineyard of Mr. C. Neate, on Stanley Flat, on the western side of the Main North Road. These vines have been planted about 20 years. They are set in rows 10ft. apart with 11ft. spaces between the vines in the rows which run approximately north and south. These spaces permit 396 vines being planted on an acre surface. The vines are trained as simple two-armed spaliers upon a trellis of medium height above the ground. The vines are all spur pruned. This season a vast number of adventitious shoots have arisen from the arms, and these have cropped freely.

The vines under test are located in a strip consisting of seven parallel rows. Of these the two outside rows and the central one act as barriers dividing the second and third, and fifth and sixth rows into two long plots. These, in turn, are divided into groups of six vines each. This was achieved by omitting the end vines in each row, and thence forward, omitting every fourth vine in the rows. These omissions constitute transverse barrier rows between the groups. In this manner 18 rectangular groups or plots of six vines each are obtained, each group being segregated by barrier rows of vines. Owing to missing vines and muscat vines having been planted in gaps, several of the test groups have not the full complement of currant vine plants. In all, five vines are missing, and the crops unrecorded from four muscat vines.

The fruit was harvested from these groups on March 21st and 22nd, 1933, the yield of each vine in each group being recorded separately by weight. The groups are distinguished by using alphabetical letters.

The following is a summary of the yields from the groups for the season 1933:—

Group.	Vine Numbers.	Total Yield of Group.	Average Yield per Vine.
		lbs.	lbs.
A	1 to 5 6 Muscat	296½	59.25
B	7 to 11 12 —Muscat	292	58.40
C	13 to 15 16—Missing 17, 18—Muscat	159½	53.17
D	19 to 24	279½	46.54
E	25 to 30	232½	38.71
F	32 to 36 31 Missing	306	61.20
G	37 to 42	299½	49.87
H	43 to 48	329	54.83
I	49 to 54	326	54.34
J	55 to 60 57 —Missing	239½	47.85
K	62 to 66 61—Missing	312½	62.45
L	67 to 72	254½	42.45
M	73 to 78 77 Missing	256	51.20
N	79 to 84	244½	40.71
O	85 to 90	331	55.17
P	91 to 96	380	63.34
Q	97 to 102	355	59.17
R	103 to 108	307½	51.21

Summary of Fresh Fruit Yields.

	lbs.	lbs.	lbs.		T.	C.	Q.	L.
99	5,199½	288.89	52.52	12.29	9	5	2	22

Summary of Dried Fruit Yields.

No. of Vines Recorded.	Total Yield Dried.	Drying Ratio.	Average per Group Dried.	Average per Vine Dried.	Rate per Acre Dried.			
	lbs.		lbs.	lbs.	lbs.	T.	C.	Q.
99	1,504	3.46 to 1	83.56	15.19	6,015	2	13	2

It will be noted that the dried currants were not graded into association grades, but as the Baume readings ranged as low as 11° and some of the fruit was poorly colored the sample must have been only fair.

In the Barossa district the crop yield test was conducted on another portion of Mr. P. B. Boehm's 9-year-old currant vineyard, planted 10ft. x 12ft., equalling 363 vines to an acre.

These vines are framed as spaliers with a single pair of arms on a low trellis, and are all spur pruned. The groups of six vines each are segregated by barrier rows as described in the Clare tests, but 25 groups were utilised. This is a very evenly grown plot from which the 150 vines have been chosen. The fruit was harvested from all of the groups on March 15th, 1933, when the Baume readings ranged from 14.5° to 16°, and averaging 15.37°.

The following is a summary of the yields of fresh currants from each of the 25 groups:—

Group.	Vine Numbers.	Total Yield of Group.	Average Yield per Vine.
		lbs.	lbs.
A	1 to 6	178½	29.75
B	7 to 12	126½	21.04
C	13 to 18	71	11.83
D	19 to 24	150¾	25.12

X	139 to 144	82¾	13.79
Y	145 to 150	107½	17.87

Number of Vines Recorded.	Total Yield.	Average Yield per Group.	Average Yield per Vine.	Yield Fresh per Acre Rate.			
	lbs.	lbs.	lbs.	lbs.	T.	C.	Q.
147	2,493¾	99.72	16.96	6.156	2	14	3 24

Unfortunately, the currants from these groups were not dried separately from the general crop, and consequently data relative to the percentages of bucks and currants of various grades are not available for the 1933 crop.

In the McLaren Flat district the crop yield test was conducted in a portion of Mr. A. C. Fraser's 11-year-old vines. These currants are planted 12ft. x 12ft., or equivalent to 302 vines per acre. They are trained on a fairly high trellis

with a cross piece on each post, and framed as spaliers, each with a single pair of arms. The arms run along the central wire, and a parallel wire passes through each of the ends of the cross pieces. The rods are tied down to these side wires. The rows run approximately east and west. The soil is strong, and the vines vigorous. Mr. Fraser states he used a heavy dressing of crude slaughterhouse refuse fertiliser, rich in nitrogen, on the land. These vines are all rod and spur pruned, some carrying as many as 13 good rods on the pair of long extended arms. The 24 groups were plotted out in a similar manner as described for the Stanley Flat and Light's Pass crop yield tests. The crop was harvested and recorded by the District Horticultural Instructor (Mr. C. H. Beaumont) on March 16th, 1933. The average Baume reading was 15.50°. The following is a summary of the respective group and vine average yields in fresh currants:—

Group.	Vine Numbers.	Total Yield of Group.	Average Yield per Vine.
A	1 to 6	138	23.00
B	7 to 12	104	17.34
C	13 to 18	158	26.34
D	19 to 24	178	29.67
E	25 to 30	165	27.50
F	31 to 36	167	27.84
G	37 to 42	132	22.00
H	43 to 48	130	21.67
I	49 to 54	152	25.34
J	55 to 60	161	26.84
K	61 to 66	120	20.00
L	67 to 72	120	20.00
M	73 to 78	70	11.67
N	79 to 84	83½	13.92
O	85 to 90	92	15.34
P	91 to 96	104	17.34
Q	97 to 102	126	21.00
R	103 to 108	112	18.67
S	109 to 114	99	16.50
T	115 to 120	79	13.17
U	121 to 126	111	18.50

Dried currants per acre rate	1.994lbs. =	C. 17	Q. 3	L. 6

HORTICULTURAL STUDIES.

In addition to the above described work of a more practical character, at the request of Mr. A. V. Lyon, M.S. Agric., certain viticultural studies were carried out on currant vines, and the data collected and recorded.

These consisted of:—

- (1) Bud studies.
- (2) Berry growths.
- (3) Shoot lengths, together with bunch counts, measurements, and weights of grapes produced on same.
- (4) Juice studies, *i.e.*, Baume readings, sugar and acid determinations.
- (5) Studies in soil moisture content.

Bud Studies were conducted upon all of the rods retained on a selected number of rod and spur pruned vines in each of the vine pruning tests in the three districts.

These observations were made after the bud burst in spring was well advanced, and the behavior of each bud from the base upwards on each rod was clearly indicated. The number of flower bunches arising from each fruiting bud was noted, and the barren and non-starting buds respectively recorded in graphic symbols.

The object of these bud studies was to ascertain if there was any consistency of behavior inherent in the buds arising from the nodes formed in any particular part or parts of the cane or rod.

Berry Growths.—The progressive growths or developments of the berries were recorded on four occasions at fairly regular intervals between the setting and harvesting. The procedure adopted consisted of picking a few berries from the shoulder, middle, and bottom of each of the bunches taken without special selection from vines in each of the groups undergoing different pruning treatments. Their developments were determined by means of water displacement in a cylinder graduated into cubic centimetres, into which 100 berries from each respective part of the bunches were dropped in separate order.

Shoot Lengths, Bunch Counts, Measurements, and Weights of Bunches.—These studies consisted of selecting a number of vines from each of the pruning test groups and measuring the length of each fruit-bearing cane, as well as the sizes of its individual bunches, and then cutting and weighing each of the bunches separately. This work was carried out when the grapes were ripe, and immediately before harvesting commenced. The object of these studies was to procure data from which might be ascertained any correlation which might exist between the growth of the shoots and the sizes and weights of the bunches of currants borne thereon.

JUICE STUDIES.

These consisted of expressing the juice from selected bunchlets of ripe currants taken from vines subject to the different pruning treatments. Readings on Baume and Brix hydrometers and determinations of acidity and sugars were made therefrom.

In the collection of the data having a bearing on the relation between shoot growths and crop yields, and studies of the comparative qualities of the juice contents of the grapes harvested from vines undergoing different pruning treatments, the officers of this Branch had the valuable assistance of Mr. Walters, of the Council for Scientific and Industrial Research Viticultural Research Station staff, at Merbein, Victoria, who made the various determinations and preliminary correlations connected with these operations requiring special skill and knowledge.

The whole of the data accumulated from the above viticultural studies have been passed over to Mr. A. V. Lyon with a view to their being statistically examined and reported upon by a specialist in such statistical work. I understand conclusions arising therefrom will, in due course, be communicated to this Branch and to the South Australian Dried Fruits Board.

SOIL MOISTURE STUDIES.

In the spring time, shortly after bud burst, a preliminary series of soil samples were taken at various depths, and their respective moisture contents determined at the Waite Agricultural Research Institute.

It was intended that, as the summer progressed and the grapes on the vines began to approach the harvesting stage, a further series should be drawn from the same positions in the plots in each district. It was considered that possibly an insufficiently sustained supply of moisture in the subsoil—such as is often experienced during an average summer in the non-irrigated currant growing districts—may influence the quality of the currants taken from such vines.

The rainfall during the winter of 1932 being more than usually heavy and the summer of 1932-33 proving to be one of the coolest on record, the supply of soil moisture was well maintained, and the vines did not show any signs of the usual effects of drought. So much was this the case that the juice of the grapes was very late in arriving at a desirable density for drying or wine-making purposes.

The Horticultural officers who have been engaged in this field work have been Messrs. C. H. Beaumont, J. B. Harris, and N. R. Quinn, whilst Mr. F. Supple, Senior Clerk, has checked over the data contained in this report, and prepared the necessary forms on which data has been set out. All of these officers have entered into the work with much intelligence and skill, and given up a good deal of their private as well as official time in assisting to make it as complete as possible.

FACTORS AFFECTING THE SEVERITY OF TAKE-ALL.

[By S. D. GARRETT, B.A., Assistant Plant Pathologist, Waite Agricultural Research Institute, University of Adelaide.]

(Continued from page 805.)

3. THE CLIMATIC FACTOR.

Although there have been numerous references to the effect of weather on take-all these have been mostly of the nature of casual observations, and many of them have been contradictory. There is, however, a general idea current among farmers in Australia that a dry summer, followed by a wet winter, is most favorable for the appearance of the disease⁽³⁾.

Two workers in America have made a limited study of the effect of weather conditions on the disease. Kirby⁽¹⁾, from a comparison of the incidence of take-all in New York State in the three years 1921-1923, concluded that the most favorable conditions for take-all were an abnormally high temperature and rainfall in early spring, followed by hot dry weather. Russell⁽⁴⁾, working in Canada with records for the seven years 1923-1929, also concluded that take-all was most prevalent in years with a wet spring, and that it was relatively scarce in years with dry spring and summer weather. He considered, however, that moist conditions right up till the time of heading were most favorable for the development of the disease, thus differing on this point from Kirby.

There appears to have been little work done yet on the actual manner in which weather may affect the prevalence of take-all. Considering the economic importance of the disease it is surprising that so little has been accomplished. The explanation is undoubtedly that the disease is influenced by so many factors that it is most difficult to control them, all so that individual ones can be studied. For instance, the life history of the causal fungus, *Ophiobolus graminis*, may be affected directly or indirectly by the weather as regards—(1) dispersal of the fungus over non-infected ground, (2) survival of the mycelium in the soil, (3) rate of spread of the mycelium through the soil, and (4) rapidity of growth of the fungus on infected plants. Moreover, each of these main divisions of the life history may in turn be affected by other factors, such, for example, as soil temperature, soil moisture, the soil microflora, &c. It is not surprising that progress in determining the main factors influencing the development of the disease has been slow and difficult.

In order to obtain as clear a picture as possible of the epidemiology of take-all each of the stages in the life history of the fungus, as enumerated above, will first be discussed. The results of an examination of past records of the disease in South Australia will then be given, and examined in the light of present knowledge.

DISPERSAL OVER NON-INFECTED GROUND.

In spite of the great practical importance of this question there is comparatively little definite information available on it. McAlpine⁽²⁾ considered that dust or wind-blown soil was responsible for much of the distribution of the fungus in parts of Australia. The spores of the take-all fungus are too delicate to withstand blowing about with dust on the hot days of summer and autumn when dust is mainly moving. There remains the possibility that particles of infected plant tissues, such as small pieces of the leaf-sheaths of diseased cereals or grasses, are carried about in the dust and form the main source of infection. This seems the most likely explanation for much of the distribution of take-all in Australia, although it is probable that the larger pieces of infected material, such as the infected barley grass stems figured by Samuel⁽⁵⁾, are chiefly responsible, rather

than minute pieces which would be included in the terms dust or wind-blown soil. (If the smaller pieces were often effective inoculum, take-all would be very much more widely destructive than it is.) Infected grass stems, dislodged by stock in neighboring paddocks during the long, dry summer, often blow over fallows, and provide centres of infection in crops sown after the first autumn rains. Growth of the fungus mycelium through the soil may then give rise to the well-known patch form of take-all.

Such infection of the soil by wind-blown plant material may well explain the appearance of take-all patches in crops sown on clean fallows, but it scarcely seems sufficient to account for the occurrence in similar paddocks of take-all in the whitehead stage as scattered plants, often so thickly interspersed throughout a crop that it becomes worthless to strip it. This form of take-all occurs only in epidemic seasons when the disease is widespread. The discovery of ascospore ejection from perithecia formed on dead plants in "primary patches" of the disease, and their dissemination by wind in rainy weather (⁶), offers a possible explanation for the occurrence of this form of the disease. However, it has not yet been completely proved that take-all can spread in this manner, and the examination of past records of the severity of the disease, together with the spring rainfall, as given below, was undertaken as a necessary step in testing this theory.

The ascospores are exceedingly delicate, and if they were carried down in rain on to a clay-loam soil it is probable that the antagonistic action of soil bacteria would prevent most, if not all of them, from germinating, or, at least, the mycelium from growing far. In agreement with this, the scattered whitehead stage of take-all has not been seen on the heavier soils, although there has only been one season as yet in which particular note could be taken of this. On the other hand, severe losses from this form of the disease are often experienced on sandy soils in seasons when the weather is favorable. On sandy soils the ascospores would more easily be washed down to the roots of plants, and since the bacterial flora of such soils is poor, and the soil temperature at the time of spore discharge is rising, it seems conceivable that ascospore infection might be rapid enough to account for the production of whiteheads in the comparatively short time before harvest. It was hoped to make a practical test of this point during the past season, but unfortunately it was not possible to produce an abundant supply of ascospores for experimental work at the time that they were needed.

This method of distribution of the fungus would be expected to occur only in certain seasons. A coincidence of several favorable conditions would be required, including conditions permitting early maturation of perithecia in the primary patches; wet spring weather suitable for ascospore ejection and infection of roots by spores carried down in the rain; and suitable conditions for rapid growth of the fungus after germination of the spores. The matter is further considered below when past records of the incidence of take-all in South Australia are discussed.

The above remarks on wind dispersal of ascospores and its possible relation to epidemics of take-all have referred to dispersal and infection during the growing period of the crop. Ascospores discharged from perithecia would certainly not last over the summer and cause infections in autumn-sown crops. It has been shown that they lose their power of germination within a few days under dry conditions (⁶). It is possible that they may last over the summer within perithecia on stubble, and be discharged when the autumn rains come. It does not seem likely, however, that they would be responsible for many of the primary infections, for there would be little wheat germinated at this time, and biological antagonism

of the soil bacteria would probably be fairly active owing to the comparatively high soil temperature, but it is certainly a point on which further information is desirable.

For the present, then, it is considered that under Australian conditions the take-all fungus is chiefly dispersed over non-infected ground in two ways—(1) by the blowing about of infected pieces¹ of stubble or grass stems during the dry summer, these pieces providing inoculum for the patch form of take-all which develops gradually in the crop, owing to the slow² growth of the fungus through the soil during the winter; (2) (in certain seasons only) by dispersal of ascospores over the growing crop when conditions have favored early maturation of perithecia, and wet spring weather has permitted wind-dissemination of ascospores and subsequent infection. In the latter case, whitehead plants appear scattered almost at random, and this form of the disease is limited to the lighter soils.

SURVIVAL OF MYCELIUM IN THE SOIL.

In Australia the period which the take-all fungus must tide over without any host to grow upon is the hot dry summer—extending usually from December to April. It has already been stated that free ascospores cannot last over this period, although they may do so within perithecia. Perithecia are often not formed at all under Australian conditions, so it is likely that most of the over-summering material consists of infected roots and stem-bases in the soil, or broken off stem bases blown about in the wind.

The amount of take-all occurring in the patch form, which is probably a measure of the amount of infective material which over-summered, varies from year to year. It would of course depend to some extent upon the amount of disease occurring in previous seasons. Nothing is known yet as to how far the heat of summer may destroy the viability of the fungus in pieces of infected stubble. But from the experimental work in the first two parts of this paper it seems likely that when rain falls during the summer there might be a considerable destruction of inoculum owing to the antagonistic effect of other soil micro-organisms towards the take-all fungus under the combination of high soil temperature and moisture. This is the explanation suggested below for the non-occurrence of a take-all epidemic in South Australia in 1917, a year in which spring rainfall appeared to be eminently suitable for the disease, but one in which there had been exceptional rains in the preceding summer. Conversely, a dry summer should permit the over-summering of more inoculum than usual, and this is in agreement with the farmer's idea of a dry summer, followed by a wet winter, being worst for the disease.

RATE OF SPREAD THROUGH THE SOIL.

Very little is known about conditions governing the rate of spread of the fungus through the soil. It is evident from the experiments described in Part I of this paper that the type of soil is of great importance; growth of the fungus must be most rapid in the light sandy soils where only a slight retarding effect is exercised by the other soil micro-organisms. In such soils, too, growth of the take-all fungus is probably accelerated by rise of temperature, whereas in the heavier soils growth may actually be checked by higher temperatures, owing to the impetus given to biological antagonism.

GROWTH OF THE FUNGUS ON INFECTED PLANTS.

So far efforts to determine whether the internal condition of the plant may influence the rate of progress of the disease have given almost negative results. The fungus was found to attack well-nourished vigorous plants at approximately the same rate as poor plants, other conditions being equal.

From the mode of growth of the take-all fungus along the outside of wheat roots, with penetration following closely behind, it would appear likely that the rate of progress of the disease on wheat plants would depend considerably on soil factors. This has, in fact, been proved experimentally. Thus the external factors, soil temperature, soil moisture, and particularly the soil microflora, acting directly on the fungus, are apparently of primary importance. It is no doubt mainly through its influence on these factors that weather is responsible for variations in time of appearance and severity of disease, rather than through any influence on the resistance of the host plant itself.

Thus the patch form of take-all, attributed to inoculum present in the soil when the crop was sown, may sometimes show up comparatively early (July-August) as a yellowing off of seedlings less than six inches high, or it may not appear until almost harvest time (October). In the latter case it appears as whiteheads, but on account of their being in definite patches there is no possibility of confusing them with the scattered whiteheads apparently due to ascospore infection in seasons favorable to aerial dissemination of the take-all fungus.

But although unfavorable weather conditions do not seem to render the wheat plant necessarily more susceptible to actual infection, they may cause the plant to succumb to the effects of infection much more rapidly. The effect of hot winds in causing the rapid bleaching off to whiteheads is a case in point. Whiteheads certainly appear in great numbers after hot north winds. Very often the take-all fungus may be established on only a few of the roots, and no sign of blackening be present on the stem. It seems likely that some toxic substance, formed as a result of the growth of the fungus on the roots, must be concerned in the rapid bleaching off, for plants in dry soils burnt off by hot winds do not bleach in the same manner. It is not yet known whether take-all infected plants protected from hot winds would bleach as suddenly as do whitehead plants in the field.

PAST RECORDS OF THE PREVALENCE OF TAKE-ALL.

From the above account of the numerous factors influencing the development of take-all it is evident that studies on the effect of weather from past records of the disease, which are usually scanty, could be expected to give only a very general picture of weather influences. Nevertheless it was desired to make an examination of past records in South Australia in order to determine whether there might be anything conflicting with the theory of epidemics being due to ascospore dispersal in seasons with wet springs.

A search was made into all available crop records from the year 1900 onwards. Three main sources of information were employed:—(1) The files of the *Advertiser*, the Adelaide daily newspaper. The entire paper was scanned for every day of the two months October and November (and in some years December was included as well) for any reference to the state of the crops. Except for the period 1918 to 1924, crop reports were sent in with regularity from all the chief country centres, and it was possible to say quite definitely whether take-all was general throughout the State in any particular year or not. (2) The *Journal of Agriculture* of South Australia. A search was made through this journal from 1900 onwards, including the reports from country Agricultural Bureaux, and any references to take-all noted. (3) Records of the Plant Pathology Laboratory, Adelaide University, available only from the year 1921 onwards.

The rainfall at Adelaide Observatory for the three spring months August, September, and October, of the years 1900 to 1933 is set out in Table IV. Years characterised by extensive occurrence of take-all are marked with an asterisk. The relation between total spring rainfall and the occurrence of take-all is also shown graphically in Figure 6.

TABLE IV.—*Rainfall at Adelaide Observatory, for the Three Spring Months of August, September, and October for the period 1900-1933.*

Years.	August.	September.	October.	Total.
1900	4.14	1.18	0.65	5.97
1901	1.12	1.48	1.59	4.19
1902	1.13	1.64	1.77	4.54
1903	2.34	2.85	0.66	5.85
1904	1.98	0.69	2.11	4.78
1905	1.48	1.51	2.90	5.89
1906*	3.97	3.37	1.66	8.93
1907	1.81	1.08	1.70	4.59
1908*	2.35	2.90	3.59	8.84
1909*	5.59	2.19	2.17	9.95
1910*	1.71	2.81	1.80	6.32
1911	0.76	3.80	0.55	5.11
1912	2.12	2.64	0.96	5.72
1913*	2.11	2.67	2.45	7.23
1914	0.35	0.60	0.17	1.12
1915*	2.53	3.57	0.67	6.77
1916	3.99	1.68	1.93	7.60
1917	3.04	3.68	2.09	8.81
1918	2.63	0.66	2.59	5.88
1919	3.07	3.05	0.77	6.89
1920	3.38	1.51	2.91	7.80
1921*	2.20	3.07	1.81	7.08
1922	2.55	1.61	1.70	5.86
1923*	2.26	5.83	2.22	10.31
1924*	2.13	3.48	2.00	7.61
1925	1.66	3.20	0.06	4.92
1926*	4.19	2.42	2.32	8.93
1927	3.79	0.91	0.48	5.18
1928	0.77	1.81	2.43	5.01
1929	1.51	2.13	1.03	4.67
1930*	3.52	2.56	2.80	8.88
1931	2.55	2.79	0.49	5.83
1932*	2.89	2.01	2.32	7.22
1933	3.36	2.89	0.64	6.89

* Years characterised by extensive occurrence of takeall.

It will be seen from Table IV and Figure 6 that there is good general correspondence between high spring rainfall and epidemics of take-all. Whereas the mean spring rainfall for the "take-all years" during the period 1900 to 1933 was 8.17in., that for the remaining years of the same period was only 5.53in., the difference being 2.64 ± 0.49 in.

Taking a rainfall of 6in. as being the approximate dividing line between "take-all years" and "non-take-all years," it is seen that there were no "take-all years" when the rainfall was below this amount, but that there were five years in which the rainfall was above this amount, but in which take-all was apparently not severe, as judged from the absence of records.

In the case of the four years 1916, 1919, 1920, and 1933, it appears as if the explanation may lie in the distribution of the rainfall. In each of these years one of the spring months was particularly dry. The years 1916 and 1920 suffered from dry Septembers, there being only 1.68 and 1.51in. of rain respectively, as against an average of 2.34in. for this month over the period 1900 to 1933. And in the years 1919 and 1933 the month of October was dry; only 0.77 and 0.64in., respectively, were recorded, as against a mean of 1.6in. for the 34-year period. Only in one of the "take-all years" did a similar dry month occur, and that was in 1915, when the October rainfall was only 0.67in., but in this case the September rain had been much above the average.

The other exceptional year was 1917, in which spring rainfall conditions were apparently suitable for the development of severe take-all, but in which no epidemic appears to have occurred. In this case the preceding summer months—January, February, and March—were remarkable for an exceptionally high rainfall of 5.34in., as against a mean of 2.58in. for the years 1900-1933. It seems possible that the combination of high soil moisture with high temperatures may have been responsible for the disappearance of most of the take-all inoculum from the soil, as a result of the antagonistic effect of soil bacteria coming strongly into play. None of the years considered as "take-all years" were preceded by such heavy summer rain as in 1917.

RELATION BETWEEN SPRING RAINFALL
AND PREVALENCE OF TAKE-ALL

Fig. 6.

Of all the "take-all" years, the year 1910 had the lowest spring rainfall, though still above 6in. This year, however, was immediately preceded by two consecutive epidemic years, 1908 and 1909, and the amount of take-all inoculum present at the beginning of the season must have been greater than usual.

Russell (⁴) reports a similar correlation between the severity of take-all under Canadian conditions and rainfall during the months of June, July, and August (which, with respect to the growing period of the crop, correspond approximately to the months of August, September, and October in South Australia). His observations are of such interest that they are quoted in full, together with his diagram (Fig. 7).

"Take-all has varied considerably in severity during the period of our investigations. This appears to be a common characteristic of the malady the world over, judging by the literature on the subject. There appears to be a marked positive correlation between the amount of rainfall occurring between the first of June and the middle of August and the severity of the disease during the same season. This fact has become apparent to us during our annual field surveys of North-eastern Saskatchewan. Figure 6 shows in the form of a chart the average of the monthly rainfall recorded at four places in North-eastern Saskatchewan during the months of June, July, and August for the years 1923 to 1929. It

can be seen that the rainfall during these months in 1924 and 1926 was very low. In 1923, 1925, and 1927 the reverse was true. In 1923 take-all was first reported in this district, and was probably fairly plentiful. Since then our annual field surveys have shown that take-all was relatively scarce in 1924 and 1926, whereas in 1925 and 1927 it was quite prevalent (see remarks concerning the prevalence of take-all in Saskatchewan in the annual reports of the Dominion Botanist for those years). During the summer of 1928, the North-eastern district of Saskatchewan was drier on the average than many other sections of the province but the precipitation varied considerably in this one district. Around Muenster, where the total rainfall for June and July was 6.22in., conditions were fairly moist and take-all was quite prevalent, whilst around Melfort, where the total precipitation was only 2.72in., the disease was much less prevalent. In 1929 the North-eastern district enjoyed relatively favorable moisture conditions as compared

Fig. 7.—Reproduced from R. C. Russell's paper, "Field Studies of Take-all in Saskatchewan."

with many other districts in Saskatchewan. The rainfall for June at all four points where records were taken was over 3in. However, there was a decided falling off in precipitation as the summer advanced, the average for July being 1.42in. and that for August being only 0.84in. Therefore, whilst the conditions were more favorable for the development of the disease than they were in many other parts of the province, yet it was so dry throughout July and the first part of August that comparatively few fields were badly affected, and the signs of the disease were not pronounced on plants which were infected."

Of particular interest is the year 1929 in Canada, which is analagous to the years 1916, 1919, 1920, and 1933 in South Australia, in showing that a well-distributed rainfall appears to be necessary for the general occurrence of the disease.

Although it is clear that there is a marked correlation between high spring rainfall and the occurrence of take-all in epidemic form, this gives only contributory evidence in support of the theory of ascospore dispersal. It is possible that the effect might be due to increased activity of take-all mycelium already present in the soil. But if this were the case it would mean that take-all could be fairly widely distributed and not reveal its presence at all in many crops unless the spring were exceptionally wet. This seems somewhat unlikely. It may be taken, therefore, that this examination of weather factors gives general support to the idea of wind dissemination of take-all in wet springs, but final proof of the theory must still be obtained by field observations on the time of ripening of perithecia, together with tests of the possibility of infecting well grown plants with ascospores under the soil-temperature and moisture conditions obtaining in susceptible localities.

SUMMARY FOR PART III.

The various ways in which weather may affect the prevalence of take-all are discussed under the headings "Dispersal of the fungus over non-infected ground," "Survival of mycelium in the soil," "Growth of mycelium through the soil," and "Infection of the plant."

The results of an investigation into the occurrence of take-all in South Australia during the years 1900 to 1933 show that epidemics occurred only in years characterised by a comparatively high spring rainfall. The possible relation of this to the occurrence of wind-borne ascospore infection on the lighter soils is discussed.

ACKNOWLEDGMENT.

This work was done under the direction of Mr. G. Samuel, to whose experience of the take-all disease this paper owes much, and to whom the writer is indebted not only for frequent suggestions and criticism during the course of the work, but also for much help in the preparation of the manuscript. In particular, he wishes to express his thanks to Mr. Samuel for making the drawings of root infection shown in Figures 1 and 5, and for permission to publish the results of the soil temperature experiment described in Part II. of this paper.

THE EFFECT OF CROP ROTATION ON THE EELWORM (*HETERODERA SCHACHTII*) DISEASE OF CEREALS.

[By S. D. GARRETT, B.A., Assistant Plant Pathologist, Waite Agricultural Research Institute, University of Adelaide.]

The eelworm disease of cereals in South Australia, caused by the nematode *Heterodera schachtii*, has already been described by Dr. James Davidson ⁽¹⁾.

The disease affects wheat, oats, and barley, and may cause a severe set-back to crops in the early stages of growth. Although in the mallee areas it usually appears in rather small and definite patches, in the better rainfall areas whole crops may be more or less uniformly affected. Usually at the time tillering should be commencing the seedlings begin to appear somewhat weak, spindly and yellowish, and if the roots are examined the presence of the eelworms is immediately evident. The most striking change is produced in wheat (Fig. 1), in which each point of entry of the nematodes eventually becomes a gall or swelling covered with a tuft of freshly formed lateral rootlets. The number of these galls upon the root system of an affected wheat plant thus gives some measure of the severity of attack. Usually as the warmer weather of spring comes on affected crops grow away from the disease and make a moderately good recovery, but instances have been known of almost complete crop failures from this cause.

During September, 1933, it was found that a combined Manurial Treatment and Crop Rotation experiment in progress at the Waite Institute (the results of which will be published elsewhere) was suffering rather severely from eelworm attack. It was therefore decided to conduct a systematic survey of the whole area for eelworm, in the hope that useful information might be obtained on the effect of crop rotation and manurial treatment upon the occurrence of the disease.

METHOD.

The experiment had been laid out in two parallel blocks of 60 plots, making 120 plots in all. Five different rotations had been employed in conjunction with four manurial treatments. Wheat was grown after wheat, barley, oats, peas, and bare fallow, respectively, and the manurial treatments were (1) no manure, (2) superphosphate, 2cwts. to the acre, (3) superphosphate, 2cwts. + ammonium sulphate, 1cwt. to the acre, (4) ammonium sulphate, 1cwt. to the acre.

The history of the experimental area from the year 1928 was as follows:—

1928	Pasture (not cropped for 10 years)
1929	Oats (whole area)
1930	Wheat, barley, oats, peas, fallow.
1931	Wheat (whole area)
1932	Wheat, barley, oats, peas, fallow
1933	Wheat (whole area)

The distribution of the different rotation crops in 1932 was exactly the same as that in 1930, i.e., a plot under wheat in 1930 was sown with wheat again in 1932. So that whilst the wheat, barley, or oat plots were carrying a susceptible crop for the fifth successive year in 1933, in the pea and bare fallow plots a susceptible crop had always been followed by a non-susceptible one (peas) or by a bare fallow.

(1) Davidson, J.: "Eelworms (*Heterodera schachtii* Schm.) Affecting Cereals in South Australia." *Jour. Agric. Sci. Aus.* 34: 378-385. (1931.)

The plots were 80yds. long by 11 drill-rows wide. They were sampled by taking 10 single plants, at intervals of approximately nine paces, from each plot. When sampling had been completed, the plants were taken to the laboratory and the roots washed free from soil. An estimation of the amount of eelworm present in each plot was then made by inspection of the root systems of the 10 sample plants. A rating, varying from 0 to 3, was allotted to each plant according to the degree of eelworm infestation of the root system:—

Very severe infestation	3 units
Severe infestation	2 units
Moderate infestation	1 unit
No infestation	0 units

Fig. 1.—Roots of wheat seedlings severely affected by the nematode (eelworm) *Heterodera schachtii*. Note the numerous small galls with tufts of lateral roots arising from them.

From the sum of the individual ratings for the 10 plants from each plot, a figure expressing percentage eelworm infestation for the whole plot was then obtained as follows:—

$$\frac{\text{Sum of individual ratings}}{10 \times 3} \times 100$$

since the maximum possible infestation would be represented by a rating of three for each of the 10 individual plants, making a total of 30. The percentage figures were only approximate, both because of the method of rating adopted and because it was not possible to take more than 10 samples per plot. In spite of this, however, the results were found to be quite clear cut.

DISCUSSION OF RESULTS

(1) *The effect of rotation.*

The data from 120 plots are summarised in Table I.

TABLE I.

Rotation.	Percentage Eelworm Infestation.						Mean.
	Block A.	Block B.	Block C.	Block D.	Block E.	Block F.	
Wheat after wheat ..	51	50	25	81	52	42	50
Wheat after barley ..	59	58	18	53	50	50	49
Wheat after oats	45	32	30	43	41	36	38
Wheat after peas	9	2	0	16	3	0	5
Wheat after fallow ..	14	13	4	0	3	3	6

In the plots following wheat, oats, and barley, which were carrying a susceptible crop for the fifth successive year, mean infestation ranged from 38 to 50 per cent. In the plots following peas and bare fallow, mean infestations of only 5 and 6 per cent. respectively were recorded. In the latter case a susceptible crop (oats in 1929, wheat in 1931) had been followed in both years by a non-susceptible crop (peas) or by bare fallow.

Since the three cereals are known to be hosts of the nematode these results are in accordance with expectation. Mr. Worsley C. Johnston, Agricultural Instructor, has also found the nematode cysts on the roots of certain grasses in the Lower Northern districts (²), so that leaving land out to pasture is not likely to be of value in ridding it of eelworm. Peas, on the other hand, are not susceptible to *Heterodera schachtii*, and so are as efficient as bare fallow in reducing the pest.

(2) *Effect of Manurial Treatment.*

The data from 120 plots are summarised in Table II. It will be seen that manurial treatment seems to have had no significant effect upon the amount of disease.

TABLE II.

Manurial Treatment.	Percentage Eelworm Infestation.					Mean.
	After Wheat.	After Barley.	After Oats.	After Peas.	After Fallow.	
O = No manure	45	41	28	6	7	25
P = Super 2 cwt.....	62	37	47	3	3	30
P.N. = Super 2 cwt. + Sulph. of						
Amm. 1 cwt.	41	45	44	3	0	27
N = Sulph. of Amm. 1 cwt. ...	40	36	32	8	14	26

CONTROL OF THE DISEASE.

The beneficial effects of bare fallow, and of the non-susceptible crop peas, are undoubtedly due to the "starving-out" effect of a year with no susceptible cereal or grass present. The great majority of the eelworm eggs hatch when the winter brings suitable moisture conditions in the soil, but the young eelworms find no host plant on which they can multiply in bare fallow or peas, and so die of starvation. It is the same principle which is at the basis of rotation of crops for the control of nearly all soil-borne diseases. The pest should never be allowed

(2) Johnston, Worsley C.: "The Occurrence of Eelworms on the Roots of Certain Grasses." *Jour. Agric. Sth. Aus.* 37: 705. (1934.)

to multiply up to large numbers in the soil as a result of growing several susceptible crops in succession; but if it has been allowed to do so, the only practicable treatment is to bare fallow, or to grow a non-susceptible crop such as peas. It is fortunate that in the case of the nematode *Heterodera schachtii* a single year's fallow or peas seems to be sufficient to reduce the disease to such a small amount that it has comparatively little effect on a following cereal crop.

SUMMARY.

In a combined manurial-rotation experiment at the Waite Institute it was found that eelworms (*Heterodera schachtii*) caused considerable injury in plots which had been under cereals for five consecutive years, whereas in plots where peas or bare fallow alternated with cereals the damage was of very small proportions. Manurial treatments of superphosphate or sulphate of ammonia had no appreciable effect on the amount of disease.

SCABBY MOUTH IN LAMBS.

Relying to a question from the Secretary of the Black Springs Branch of the Agricultural Bureau as to the cause and cure for scabby mouth in lambs, Mr. R. H. F. Macindoe, B.V.Sc., M.R.C.V.S., Deputy Chief Inspector of Stock, says this is an infectious disease and is brought about by infection of the skin with a very small organism (ultra-visible group) especially if the skin has been injured. It occurs only in sheep and goats and may occur at any age, but one attack confers an immunity.

It may be seen in the skin around nostrils and eyes, skin of cornet, skin of udder, and the lining membranes of the lips, gums, palate, and tongue. The affection runs a course of from 15 to 23 days from the time the animal becomes infected until recovery takes place. The death rate is small, but animals lose condition owing to

“Scabby Mouth”—Sheep and lambs affected on the muzzles.

interference with their feeding. *Treatment*—Affected animals should be removed from rest of the flock, but this is often impracticable owing to the fact that by the time the disease has been noticed it may have got too great a hold, and the majority of the flock either show the lesions of the disease or will do so a few days later. The local treatment is to apply an oily dressing to affected parts and the earlier it is applied the better. A good dressing to apply is a carbolic ointment, 2 per cent. strength. This is applied and rubbed in after removing any loose scabs with a piece of smooth, flat stick. One dressing is often sufficient, but in severe cases it may be necessary to redress the sheep in a few days' time. The application of Stockholm tar instead of an ointment is also useful.

WHEAT VARIETIES RECOMMENDED FOR VARIOUS DISTRICTS.

[By R. C. SCOTT, Supervisor of Experimental Work.]

The Government Statist records that 244 varieties of wheat were planted in South Australia during the season 1932-1933. This is a large number, and it is certain that many of those listed could with advantage have been replaced by more suitable types.

At the same time, if improved varieties are to be developed, new crossbred or selected wheats recently liberated from plant breeding stations must always be tested under average field conditions before their value can be ascertained. Consequently, such a list must always include those planted for experimental purposes.

However, examination of the return referred to clearly indicates that many wheats whose limitations so far as yield, disease-resistance, &c., are well known are still being fairly extensively planted, and should be discarded with advantage to both the farmer concerned and the State as a whole. It costs no more to plant a suitable than an unsuitable variety, and information regarding the most valuable wheats for the different districts in South Australia is of special interest.

Following upon a resolution passed at the Conference of Upper South-Eastern Branches of the Agricultural Bureau held at Bordertown last year the agricultural instructors were asked to report upon the varieties that had proved the most suitable and highest yielders under the varying soil and climatic conditions obtaining in their respective districts. An outline of these reports is submitted below:—

CENTRAL DISTRICT.

Including Counties Adelaide, Sturt, Hindmarsh, Fergusson, and Carnarvon. (Instructor, Mr. R. Hill.)

Yorke Peninsula.—Ford, Sword, Nabawa, Raneë.

Salisbury to Gawler.—Sultan, Nabawa, Ford.

Palmer to Monarto, Brinkley.—Nabawa, Ford, Raneë.

Strathalbyn and Hartley.—Nugget, Nabawa, Ford, Sultan.

Remarks.—"It was during the dry seasons that Nabawa came into prominence, and this variety is very popular in practically all districts. However, the most consistent yielder has been Ford, whilst at the present time Sword promises to become the outstanding variety both for yield and disease resistance. Raneë has yielded well throughout the district, and will become more popular as the improved selection, Raneë 4H, becomes distributed. On account of its susceptibility to rust, Sultan is losing popularity."

LOWER NORTH.

Including Counties Daly, Stanley, Burra, Gawler, Light, Eyre. (Instructor, Mr. W. C. Johnston.)

Low Rainfall Districts (12in. to 14in.).—Gluyas, Waratah, Nabawa, Sword, Ford.

Intermediate Rainfall Districts (14in. to 16in.).—Waratah, Sword, Ford, Nabawa, Raneë.

High Rainfall Districts (over 16in.).—Gallipoli, Raneë, Ghurka.

Remarks.—"Very wide variations of soil and rainfall occur in this district. For the areas of low rainfall Gluyas must be retained, because of its drought-resisting powers, whilst Waratah is also highly suited to such conditions. For the limestone types of soil there does not appear to be any variety better than Ford, whilst this wheat is also recommended for those districts in which there is

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)	
F. COLEMAN, J.P.	A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc.	PROF. A. J. PERKINS
D. A. LYALL, ESQ.	W. J. ADEY, ESQ.
H. C. PRITCHARD, A.F.I.A. (SECRETARY)	

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,

Agricultural College,

ROSEWORTHY.

danger of rust. On the best wheatgrowing land and in the districts of regular rainfall Federation was originally the most popular variety, but to-day this wheat has been largely replaced by Gallipoli. Ranee has also gained favor for these conditions, and appears to be very well suited to the red type of soil."

UPPER NORTH.

Including Counties Kimberley, Victoria, Dalhousie, Frome, Granville, Newcastle, Hanson, Blachford, Taunton. (Instructor, Mr. E. L. Orchard.).

Far Northern Districts.—Hawker, Willochra, Quorn, Willowie:—Ranee, Nabawa, Federation, Waratah, Ghurka.

Western Districts.—Baroota, Telowie, Nelshaby, Warnertown, Wandearah, Crystal Brook:—Nabawa, Ford, Quality, Currawa, Gluyas, Sultan.

Eastern foothill country from Melrose through to Laura:—Ford, Sword, Nabawa, Ranee, Caliph, Sultan, Gallipoli.

Centre Northern Districts.—Beetaloo, Gladstone, Jamestown, Belalie:—Gallipoli, Sword, Ford, Nabawa, Ranee, Ghurka, Waratah, Dan.

Mid-Northern.—Bundaleer, Georgetown, Gulnare, Narridy:—Ford, Sword, Nabawa, Ranee, Aussie, Sultan, Gallipoli.

SOUTH-EASTERN.

Including Counties Grey, Robe, McDonnell, Buckingham, Cardwell. (Instructor, Mr. E. S. Alcock.)

Tatiara and Naracoorte District.—Gallipoli, Ranee, Ghurka.

Drained Area.—Gallipoli, Major, Huff's Imperial, Bunyip.

Volcanic Area.—Zealand Blue, Major.

Remarks.—"Very little wheat is grown on the volcanic land. On the wet, black lands in the drainage area the early-maturing wheat, Bunyip, is utilised for late seeding."

MURRAY MALLEE.

Including Counties Chandos, Buccleuch, Russell, Alfred, Albert, Hamley, Young, (Instructor, Mr. R. L. Griffiths.)

The wheat varieties which have proved most suitable and productive in the Murray Mallee Districts are:—

Gallipoli: At present appears to be the most popular variety throughout the better rainfall parts of the district. Has proved very successful when sown sufficiently early.

Ranee: Very popular in Chandos District, now increasing in popularity throughout the whole of the Murray Mallee. New selection Ranee 4H superior to earlier selections, very suitable for mid-season seedings.

Nabawa: Popular throughout the whole district. More suitable for the low rainfall parts than elsewhere. Finished badly this season, and many crops lodged rather badly last season (1932-33).

Sword: Not largely grown yet, but increasing in popularity each season. Appears very suitable throughout whole district.

Waratah: Increasing in popularity throughout whole district. Appears very suitable for late seedings.

Gluyas and Late Gluyas: Replaced during late years largely by other varieties, but still good wheats, especially on new or poorly-prepared land.

Currawa and Joffre: Have been very popular for early and mid-season seedings; more suitable for better rainfall parts than in north of district. Have done very well on sandy soils. Now largely replaced by Gallipoli.

Caliph: Never very popular, but where grown has been quite successful. Discarded by many farmers on account of rust susceptibility.

Sultan: Was for a time the most popular wheat. Proved suitable throughout the district; chief fault, susceptibility to rust. Now replaced largely by Nabawa.

Ford: Became very popular for a time, but was discarded by most farmers although a few appear to grow it successfully. Probably needs more steady ripening conditions than are usual in the Mallee.

LOWER EYRE'S PENINSULA.

Including Counties Flinders, Jervois, Musgrave, York, Buxton. (Instructor, Mr. H. D. M. Adams.)

Higher Rainfall Areas of County Flinders.—Major, Currawa, Gallipoli, Ford, Rancee.

Medium Rainfall Areas.—Nabawa, Waratah, Rancee, Felix.

Light Rainfall Areas.—Gluyas, Waratah, Aussie, Canberra.

Remarks.—"Felix was grown extensively until 1932 when rust played havoc with it, and a much-reduced area was planted last year. During the season just past Waratah was the outstanding wheat in County Jervois, whilst it has also done exceptionally well in County Buxton, where it has displaced Gluyas as the most popular variety. Gallipoli and Ford have recently lost favor as they appear to suffer considerably if unfavorable weather is experienced in October.

"Nabawa is a fairly popular wheat, but is not favored to the same extent as previously, because of the general opinion that it is more susceptible to take-all than other varieties.

"Of the new varieties Sword is most promising, and the small acreage planted last season yielded particularly well."

UPPER EYRE'S PENINSULA.

Including Counties Bosanquet, Le Hunte, Robinson, Dufferin, Way, Kintore, Hopetoun. (Instructor, Mr. W. H. Brownrigg.)

Remarks.—"As the climatic conditions in this district are very similar throughout, and the wheats appear able to adapt themselves to the various soil classes, I find it hard to divide the district, and in general would place the wheat varieties for Upper Eyre's Peninsula in the following order:—Nabawa, Gluyas, Ford, Waratah, Sword, Sultan, Gallipoli, Merriden, Canberra. The outstanding wheat for both yield and weight is Nabawa. During the past four years this wheat has come right to the fore, and appears to yield well under the most adverse conditions. During the rusty year it showed a decided resistance to the disease, and even when apparently badly affected set grain, which although smaller in size, was nevertheless plump.

"Gluyas is still extensively sown in all districts, and under good farming conditions has yielded up to 36bush. per acre this year. Ford, although requiring a little longer to develop, is giving good results, and apparently has the ability to adapt itself to a variety of soils. Sword has only recently been introduced, but is showing great promise, and will be extensively sown from now on."

From the foregoing it is evident that the number of wheat varieties which can be confidently recommended for general planting under the varying agricultural conditions in South Australia is relatively limited.

As an experiment new wheats may be included in the cropping programme, but when this is done the area so planted should be small until such time as their value for that particular locality is clearly demonstrated.

In the same way those men who are still regularly planting wheats which are not included in the above lists should endeavor to test the varieties recommended, since the experience of practical farmers has indicated that they are more suitable and productive than the types previously seeded.

FERTILISERS ACT, 1918—ANALYSES OF FERTILISERS.

Following are results of analyses obtained by the Government Agricultural Analyst from samples procured by Inspectors of Fertilisers during the year ended December 31st, 1933.

NOTE.—Deficiencies greater than permitted under Section 12 of the Act are shown in *bold type*.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

CONFERENCE OF RIVER MURRAY SWAMP SETTLERS.

The third Annual Conference of settlers in the Irrigated Swamps of the River Murray was held at Murray Bridge on February 15th, 1934. Messrs. A. J. Cooke and P. J. Bailly (Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert) R. L. Griffiths, R. Hill, and P. H. Suter (District Instructors), H. Trumble, M.Sc. (Waite Research Institute), and F. C. Richards (Assistant Secretary, Agricultural Bureau), were present.

Delegates were present from Brinkley, Jervois, Mypolonga, Gumeracha, Monarto South, and Murray Bridge Branches. Mr. A. Wells (Chairman of the Murray Bridge Branch), presided, and the Opening Address was delivered by Mr. P. J. Bailly.

Mr. F. Lehmann (Murray Bridge) read a paper on "Butter Prices." In the discussion that followed it was decided:—"That this Conference requests the Government to instruct the recently appointed Dairy Committee to find out from the factories the reason for the difference between the price paid to the producer for butter-fat and the price paid for butter by the consumer."

Conference discussed the question of the formation of a Veterinary Lodge for the Swamp areas, and it was resolved—"That a local committee be appointed with a view to placing before settlers on the Swamps the advantages of forming a Veterinary Lodge." The following committee was appointed:—Messrs. H. B. Kuchel (Murray Bridge, J. W. Schultz (Jervois), P. H. Pickering (Mypolonga), W. Baldock (Long Flat), C. F. Altmann (Monarto South), H. Mountstephen (Monteith), E. W. Pearson (Brinkley), and F. Burr (Honorary Secretary).

The following addresses were delivered:—"Production of Pigs for Export," Mr. H. B. Barlow; "Poultry as a Sideline on the Swamps," Mr. C. F. Anderson.

It was decided:—"That the 1935 Conference should be held at Murray Bridge, with the arrangements in the hands of the Jervois Branch."

The Evening Session was occupied with an address, illustrated by lantern slides—"The Establishment and Management of Irrigated Pastures," by Mr. H. C. Trumble.

CONFERENCE OF LOWER NORTH BRANCHES.

The Annual Conference of Lower North Branches held at Riverton on February 22nd was opened to an excellent attendance of delegates from the Saddleworth, Riverton, Tarlee, Wasleys, Roseworthy, Blyth, Owen, Dudley, Alma, Kapunda, Farrell's Flat, Greenock, Rhynie, Penwortham, Everard East, Buchanan, Stanley Flat, Watervale, and Wirrilla Branches of the Agricultural Bureau by Mr. F. Coleman (Member of the Advisory Board of Agriculture), who said he wanted to open this Conference with a note of optimism. An optimist sees an opportunity in every difficulty, while a pessimist sees only difficulties in every opportunity. No depression lasts for ever; values will surely stabilise on safer surer lines. Work and prudent economy have killed every depression in the past, and will win out this depression, too. Some people talk of over-production; I do not believe it for a moment; I do not believe it is even in sight. That there is under-consumption is granted, for there are millions in Europe alone to-day who are under-fed and under-nourished. There is need, a crying need, for freer interchange between countries, of foodstuffs and the essentials for healthy life.

In the first place it is necessary to recognise clearly the relative value of the Primary to the Secondary Industries. Situated as Australia is to-day, and especially South Australia, with overseas liabilities, with debts and interest charges, how are

those liabilities to be met honorably except through exports of primary products, for under our industrial conditions there is no possible chance of exporting manufactured goods in any quantity, in competition with the rest of the world.

If, then, the great primary products, such as wool, wheat, dairy produce, fruit, etc., from this State are to continue to be raised, it must not be below the actual cost of production. The producer must be able to live and remain solvent. The Australian protective policy of the past 33 years has added to the cost of production of wheat, etc. The remedy lies in reducing these high tariffs to that of a purely revenue tariff of, say, 10 per cent., which with the long freight charges should be protection enough to hold the local market. If not, then the great primary industries will be crippled, which must of necessity react upon the secondary industries already well established. Without the "new money" obtained from the sale of primary products won from the soil it will not be possible to pay overseas commitments, nor purchase the factory goods turned out by the secondary industries.

If the reduction of the tariff is not practical, then the alternative seems to be the fixing of an artificial price for the home, i.e., the Australian market. This is now being actually considered in regard to butter. The price of butter in New Zealand to-day is, say, 7d., freight to Australia 1d., duty on butter 6d. a lb. To import New Zealand butter, therefore, would cost 1s. 2d. landed here. A Board—termed the Commonwealth Dairy Produce Equilisation Committee—will then fix the price of butter for the whole of Australia at 1s. 2d. a lb. A quota for export will be declared each week, say 50 per cent. of the butter manufactured; that will bring say 7d. a lb. f.o.b., as the balance is used locally at 1s. 2d.; the average price to the dairy farmer will be the mean between 7d. and 1s. 2d. = 10½d. per lb., the price rising or falling as the London prices rises or falls. That is the proposal on which is based the Dried Fruits Acts.

South Australia has until the 1st of March to come into this new scheme, which the Commonwealth, Queensland, New South Wales, Victoria, and Tasmania have agreed upon; these States produce 94 per cent. of the butter made in Australia, while South Australia produces only 4 per cent. and Western Australia 2 per cent. The Paterson Scheme expires on March 1st. Attempts at price fixing and Government control will not tend to lessen the cost of production. The surer way to develop an industry is to reduce the cost of its products.

So far as the dairying industry is concerned, I believe that by care in breeding and feeding it is possible to produce butterfat at 6d. to 8d. a lb. in this district in an average year, and at less cost in good seasons.

Professor Perkins in evidence before the Federal Grants Commission said: "If Port Adelaide were a free port, even wheat at 2s. per bushel would not necessarily be a losing proposition." It is along the lines of lessened cost of production that I look for relief; efforts to bolster up a position by bounties, levies, schemes, or subsidies are wrong.

Overseas markets must be developed. Denmark has a slogan that their produce "*must look better and taste better than any similar product in the world,*" and we need to adopt a similar slogan. We need to watch our Eastern markets for wheat. China and Japan want our wheat, but we must insist on uniform quality in those Eastern countries, just as much as with our butter, lambs, eggs, or fruit in the English market. Our flour has latterly tended to deteriorate in gluten content, and Dr. Callaghan at Roseworthy is alive to this weakness. The New South Wales Department of Agriculture is also working along the lines of improved mill-quality.

If costs of production can be reduced by raising more and better quality per acre, through better farming practice, better soil tillage, better varieties of cereals, better strains of livestock yielding better butterfat returns, better lambs through improved pastures through top-dressing, and cultivated grasses and clovers. If these are

marketed at a uniform standard of quality, South Australians can hold their own in the open markets of the world, if given a fair chance, unhandicapped by high tariff duties.

Bureau officials present were Messrs. A. L. McEwin (Members of the Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), C. F. Anderson (Government Poultry Expert), W. C. Johnston, H. J. Apps, and J. B. Harris (District Instructors), C. A. Goddard (Assistant Wool Instructor of the School of Mines), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

Mr. D. C. Hannaford, President of the Riverton Branch, occupied the chair, and during the course of the Conference the following papers were read and discussed:—“Power Farming,” E. Travers (Rhynie); “Wool and its Classes,” G. E. Wait (Rhynie); “Pasture Improvement and Grazing,” J. Stephenson (Penwortham); “Crop Rotations,” F. W. Coleman (Saddleworth); and a wide variety of questions was discussed by departmental officers.

Mr. Spafford addressed the Conference on the subject of “Export Lambs.”

Life Membership Certificates of the Agricultural Bureau were presented by Mr. A. L. McEwin to Messrs. E. A. Gray and J. P. Schultz, who have been associated with the Agricultural Bureau for over 20 years. In expressing thanks for the honor that had been conferred upon him, Mr. Gray said the Riverton Branch was formed on December 23rd, 1889, with the following gentlemen as foundation members:—Dr. F. Allwood (Chairman), Messrs. F. Norton (Secretary), F. Gray, J. Cooper, and J. Kelly. The Branch was reformed on October 21st, 1911, and Mr. Gray was elected Honorary Secretary, a position he occupied until 1929. He acknowledged the support of those members who had for so long been associated with the Branch, and trusted that the younger members would push on the work of the Bureau and endeavor to make the Branch worthy of the Riverton district.

Mr. McEwin also handed the trophies to the successful competitors in the Midlands Crop Competition. These were as follows:—First, H. Michael (Hilltown)—Dan, 42bush. to the acre, 92 points; second, O. V. Roberts (Spalding)—Dan, 45bush. to the acre, 91.5 points; third, S. Garrard (Farrell’s Flat)—Gallipoli, 43bush. to the acre, 91 points.

Conference adopted the following resolution:—“It was decided that the 1935 Conference should be held at Blyth.”

Conference concluded by an address, “Modern Methods of Keeping Poultry,” by Mr. C. F. Anderson.

The Committee of the Riverton Branch, and in particular the Honorary Secretary (Mr. O. E. Longbottom) are to be congratulated on the success which attended their efforts of the organisation of the Conference.

CONFERENCE OF YORKE PENINSULA BRANCHES.

Mr. O. H. Heinrich, Chairman of the South Kilkerran Branch, presided over a very good attendance of delegates from the Wauraltee, Kilkerran, Arthurton, Weavers, Brentwood, Boor’s Plains, and South Kilkerran Branches at the Annual Conference of Yorke Peninsula Branches held at Port Victoria on March 7th.

Mr. A. L. McEwin (member of the Advisory Board of Agriculture) delivered the opening address. The Department of Agriculture was represented by Prof. Arthur J. Perkins (Director of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), R. C. Scott (Supervisor of Experimental Work), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

The following papers were read:—"Woolelassing," R. O. Castine (Wauralte); "Transportation of Sheep," O. H. Heinrich (South Kilkerran); "Bulk Handling of Wheat," M. D. Wright (Boor's Plains); "Pig Feeding," A. P. Robertson (Wauralte); "Sheep *versus* Wheat," M. Newbold (Wauralte). Mr. Scott gave a review of the Barley Experimental Plots being conducted on Yorke Peninsula.

Conference carried the following resolutions:—"That Parliament be asked to alter the time of burning stubble in agricultural districts from 2 p.m. until 8 a.m." "That the Government be asked to appoint a veterinary surgeon to the staff of the Department of Agriculture, whose services should be made available to members of the Agricultural Bureau." "It was decided that the 1935 Conference should be held at Kadina, the arrangements to be in the hands of the Boor's Plains Branch." Delegates were entertained at luncheon by the ladies of the district.

The evening session was occupied with an address illustrated with moving pictures on "The Petroleum Industry" by Mr. B. B. Crewe, of the Vacuum Oil Company.

Mr. M. Newbold ably carried out the secretarial duties of the Conference.

BUTTER PRICES.

[By F. LEHMANN, Murray Bridge.]

River Murray Swamp Settlers Conference, Murray Bridge, February 15th.

It is by comparing butter price figures, past and present, that a clearer conception of the value of dairy products is obtained. In this paper the figures quoted show the fluctuations of the dairyman's wages.

The average price per lb. of commercial butter sold by me during the last 23 years has been 1s. 3½d. per lb. net on the farm. The highest price was during 1921, when it averaged 2s. 1d. per lb. During the year 1933, ended June 30th, it averaged 8½d. per lb., and for the year December 31st, 1933, 7½d. per lb.—just half the average for 23 years.

PRICES OF COMMERCIAL BUTTER AT CALLINGTON

*Chart showing Rises and Falls for 23 Years
1911 to 1933*

Butter Manufacturer's Charges.

In 1911 all charges for freight, making, and commission were 2d. per lb. In 1923 all charges for freight, making, and commission were 2½d. per lb. In 1925 all charges for freight, making, and commission were 2½d. per lb. In 1928 all charges, including stabilisation levies, were 4½d. per lb. In 1930 all charges, including stabilisation levies,

were 4½d. per lb. February, 1934, 7½d. lb. butterfat, or 6½d. lb. commercial butter (1s. 2d. in prints), 8½d. per lb. 1933, from producer to consumer, total 9d. per lb. In October, 1925, 100lbs. cost £1 0s. 11d. to prepare for market, or 2½d. per lb. The storekeeper paid 1s. 5½d. per lb., the consumer 1s. 8d., the producer got 1s. 2½d. per lb. for commercial butter, the margin being 5½d. per lb.

The following figures show what becomes of the 100lbs. of butterfat the dairyman sells to the butter maker. These are figures for the first week of February, 1934:— 100lbs. of butterfat at 7½d. per lb., £3 4s. 7d., makes 118lbs. commercial butter, sold in prints at 1s. 2d., £6 17s. 8d.; 118lbs. commercial butter sold to consumer at 1s. 4d., £7 17s. 4d. The butter manufacturer obtains £3 13s. 1d. more for the 100lbs. than he gives the producer, or 8½d. per lb. on 100lbs. butterfat to cover costs of making, &c., another 2d. per lb. for the retailer's charges, leaves a total margin of 10½d. per lb.

The above figures compared with the 1925 costs of 5½d. per lb. are rather disturbing.

If this is due to the burden of price disparities because of high tariffs and low export prices, it is the duty of dairymen to get butter or dairy produce values on a parity with goods that others in the community supply us with. The question is: How is this to be done, Producers must organise and unite to gain their aims by moral means; they must realise that conditions are changing; and should not estimate the policy of the future by a summary of the past.

The farmer of the future will have to be respected and his welfare cherished in accordance with his value to the community. It is essential, therefore, that farmers create respect, and as a guarantee of good faith, organise the primary industries in a manner compatible with their value to the Nation. If their efforts are sincere, painstaking, and fearless, the people will respond. They will realise that any real and lasting adjustment of the industrial and economic position must proceed from some redeeming influence, consistent with rural industrial organisation, associated with economic government.

During October, 1925, butter factory charges for making and commission was 2½d. per lb., and 2½d. extra to the consumer, a total of 5½d. against 10½d. as at present. This wide margin leaves ample room for dairymen and small factories to compete and make a good profit, and by giving a little more for cream, get their supplies. This is the national result of present conditions, therefore dairymen should get the best talent available to put the dairying industry on a profitable footing.

CLASSING SMALL CLIPS.

[By S. WAITE, Rhynie.]

Money is lost and disappointment caused in prices obtained for wool, principally through faulty classing. Small growers should give more careful attention to the get-up of their clip no matter how small, and the following information should be helpful:—

When the fleece is shorn off, the belly wool should be kept separate, and it is essential that the fleece be thrown out and spread well on a large table. Heavy skirting is not necessary. Most small growers make the mistake of tearing off wool right around the fleece. This should not be done. Only a light trimming is necessary. The main points to take off are the sweat edge under the arm and the short wool from the fore and hind legs and any stained breech wool. Only one class of pieces should then be made, keeping the stained pieces separate. In classing the fleece of a small Merino clip it is not practical to make a large number of sorts. Over-classing a small clip and cutting it up into "Star" lot parcels is a mistake. Providing the sheep are bred on fairly even lines and have been grazing on the same pasture, the larger number of bales that can be made of a sort the better. That the fleece must not be torn apart is a mistaken idea. The modern method is to strip out the middle of the fleece—commonly known as the backwool—and roll this up as a separate fleece, thereby making

one fleece of the good, long shafty shoulder, side and breech wool, and another fleece of the back wool. By doing this the wool practically classes itself. The best wool brand "AA" and the back wool brand "A." Some growers think that if a back wool is not dusty it should not be taken out. This is a mistake. Very few sheep grow a back wool equal to that on the sides, shoulder, and neck. It is generally weather-affected, shorter in staple, tender, and is inferior to the other portion of the fleece. There can be no effective classing if the back wool is not taken out. To keep the "AA" line even in length and condition, any short, yellow or tender fleece can be put with the "A" class. This leaves the "AA" wool of even and good length, and which is generally known to the buying trade as "Spinners" wool. The "A" class is known to the trade as "topmaking" wool. These wools are used for entirely different purposes in manufacture, and when the fleece is rolled up without taking the back out the grower is offering to the buyer two entirely different wools. The "spinner" buyer cannot operate owing to the presence of the "topmaking" wool. The wool is therefore bought by the topmaking buyer, who eventually sorts it and makes a good deal of money out of the unclassified wools. In the first place the good wool is bought at the topmaking price and there is no doubt that much of the spinners' wool is afterwards resold at good profits. If the back wool is dusty or earthy, it is still more important that it be taken out for the reason that the sand or dust drifts through the whole of the wool when being handled, both in packing and when shown on the show floor. All the clean wool becomes dusty and is unattractive generally to overseas buyers.

It is not necessary to keep hogget, wether, and ewes' wool separate, provided they are bred on the same lines and run on similar pasture. It is far better to mix the sexes and class the wool as suggested.

Estimate the amount of fleece wool the flock will cut in determining the number of packs and weight to be put into same. For instance, if 50 sheep are shorn at an average weight of 10lbs. per head, equalling 500lbs., or, say, two bales, do not make one bale 400lbs. weight and the other 100lbs. weight. Make two bales of 250lbs. each. A 250lb. bale is the minimum weight of a shipping bale. Any bale weighing less than this is sold as a light weight bale and is generally bought by dealers. Do not press the wool into three bales to save the cost of a pack. If possible avoid mixed bales, but if unavoidable advise the broker of any bales that contain mixed wool or enclosures. Do not sew the bales with binder twine. Use a good sewing twine or wire bale fasteners. Brand the bales with a good stencil plate on the front, side, and top of bale. The front side of the long 54in. fixed top pack means the side directly opposite the hinge or fixed side of the cap. Leave the bottom of the bales clean for the buyers' countermark and port mark of destination.

Bulk-classing or pooling for the small grower is now an established practice with all wool brokers. This method of marketing is proving most successful. All mixed bales, packets, and bags are not now sold without bulk-classing. Bulking promotes competition and enhances values, but it is very difficult for the broker to successfully re-class fleece wool, in which the grower has left the back wool.

Inter-lotting is another modern method which has proved a great advantage to the grower. It means grouping various brands together of similar types of wool to make large lines that come in for competition from overseas buyers in the big selling room.

Small growers also make the mistake of not classing lambs' wool. A sheet should be placed over the rolling table and all lambs fleeces put over the table. By using the two hands lightly and picking up the lightest and longest stapled wool, the shorter lambs' wool is left on the table. Two sorts should always be made.

It is not necessary for the farmer to have a scientific knowledge of wool in order to put up his clip in an attractive manner. Wool-classing is only matching, and if the wool grower will match all the long stapled wool together and the short stapled wool together—provided the wool is bred on fairly even lines—it is all that is necessary and is only a common sense job.

Growers should always advise their brokers when consigning their wool as to the manner in which the clip has been put together, and give specifications regarding the number of bales of each description of wool.

POWER FARMING.

[By E. TRAVERS, Rhynie.]

About 30 years ago the internal combustion engine made its appearance in the motor car on Australian roads, and by the year 1916 began seriously to challenge the light horse.

The improvements in the internal combustion engine and the improved methods of manufacture, and repairs of same, since that date, have developed the farm tractor to such an extent that the draught horse has now to take second place to the tractor, as a more economical and more efficient method of farming. For the last 22 years I have put under crop from 400 to 500 acres each year. When farming with horses I sowed 400 acres of fallow each year and kept from 20 to 22 draught horses to do the work.

The general practice adopted by me since using the tractor is as follows:—Fallowing in winter; cultivating twice in spring; harrowing after rain during summer; working the fallow twice again with the combine at seeding, and at harvesting: seven times in all.

I maintain that it requires five working horses per 100 acres. A tractor with a draw-bar pull which will displace from 12 to 14 horses is taken for purposes of comparison. Such a tractor will work comfortably 500 acres each year, and to work 500 acres—seven times over the land—requires 25 good horses.

The tractor has an advantage over horses at busy periods when the land is in the most suitable condition for working. One tractor can do more work in a day with two men driving it than two horse teams, which is an advantage, for wheat sown under the best conditions gives the best results. One tractor and a 10ft. header can harvest as much wheat in a day as two 8ft. headers and four teams each of six horses. And a £330 motor truck can deliver more wheat to the railway siding than the horse teams can per day. Although this reference has been made to the motor truck, it is more profitable for the power farmer to "let" his heavy carting, and have a light truck, converted old car, or trailer, to keep his tractor going on the farm.

Another advantage in favor of the tractor is that the land can be kept cleaner, because horses have a tendency to spread weeds. There is less drudgery with power farming; when the farmer leaves his tractor his day's work is done—there are no horses to be fed after tea and on Sunday. If thorough overhauls and repairs are made, once in the slack time of each year, and then before each season's work, the tractor will be found very reliable. I have had but three stops for repairs over a working period of 11 years; two of the breakdowns took two days each to repair, and one a week.

The figures given below show the costs of both methods of farming, each plant being regarded as new. The tractor, &c., can be bought in the second-hand market as well as the goods for the horse plant. A tractor is not like a motor car, it will go on working so long as spare parts are put into it when required, and such a tractor need not be put aside until it is replaced by the diesel type of engine, which has made its successful appearance in our district. With the horse farmer, the money is not actually paid out, but the hay cut displaces wheat, and the grass grazed displaces cattle and sheep.

Wheat has been valued at 3s. 4d. per bushel at the railway siding 75 miles from port, for wheat cannot be produced profitably in Australia by either method under that price.

The above working of the land in good heavy country should give an average of seven bags of wheat and two tons of hay per acre over a period of years.

TRACTOR v. HORSES ON THE FARM.

	£	s.	d.		£	s.	d.
Tractor	575	0	0	25 horses at £27 each	675	0	0
Tractor attachments	30	0	0	Harness, swings, chains, &c., at £3 each	75	0	0
Kero., and petrol drums, pump, &c.	7	10	0	Six h.p. engine No. 4 chaff- cutter, &c.	120	0	0

					£2,083	5	0

WORKING EXPENSES.

	£	s.	d.		£	s.	d.
2,000galls. kerosene at 1s. 1d. gallon	108	6	0	Hay, bran, oats, and grass for 25 horses at 30lbs. feed per day	230	0	0
550galls. petrol at 1s. 4d. gallon	36	13	0	Shoeing and other expenses for horses	7	10	0
120galls. cylinder oil at 5s. 6d. gallon	33	0	0	Repairs and upkeep of har- ness (above depreciation) . .	5	0	0
Gear oil and grease	3	0	0	Fuel and oil for engine	3	0	0
Motor truck, tyres, tax, and licence	13	10	0	Wages for permanent man at £3	156	0	0
Repairs to tractor and truck (twice the amount it has cost me per year for 11 years)	54	0	0	Wages for extra man, 20 weeks at £3	60	0	0
Wages for farm labor (20 weeks) at £3 per week	60	0	0	Interest on above plant at 5 per cent.	104	2	0
Depreciation on above plant at 9 per cent. (11 years) . . .	138	10	0	Depreciation on above plant at 6 per cent.	125	0	0
Interest on above plant at 5 per cent.	77	0	0				
£523 19 0					£690	12	0

Balance in favor of the tractor, £166 13s.

From the foregoing figures it will be seen that with wheat at 3s. 4d. a bushel, the tractor is the more profitable. Depreciation has been allowed for at the rate of 6 per cent. (16 years 8 months) to renew the horses as well as the rest of the plant,

and depreciation on the tractor at 9 per cent. (11 years 1 month) which would allow the tractor to be renewed at any time over 8 years. Direct taxes have not been deducted from the tractor, for it is most unfair to ask power farmers to pay over 7d. a gallon on petrol, 9d. a gallon on oil, primage and sales tax added, and primage on kerosene solely for the purpose of working their land.

The advantage of the power farmer of the future will be much greater than that of the horse farmer, for the tractor and the motor truck will be very much improved as time goes on, whereas the draught horse of to-day can do very little more work than the horse of 30 years ago, and little or no more work can be expected from the horse of the future. No tractor was a success until the high-speed engine was introduced. The Diesel engine with its low grade fuel has completely shifted the steam engines from the railways of Denmark and Holland and is slowly challenging the steam trains of England, France, and Germany. The Diesel tractor is doing the work of 16 horses at 1½ galls. of crude oil per hour at 5½d. per gallon, and each hour of its work it is doing one-third more work in the hour than my tractor, which uses 17 to 18 pints of fuel per hour, from which I have taken my calculations and figures above.

CROP ROTATIONS.

[By F. WATSON COLEMAN, Saddleworth.]

With the continual low prices of wheat and other cereals, and the improvement in the prices for wool, it would seem that we should go in for wool instead of wheat. This probably will be done on some of the larger holdings, but on average sized farms it is not possible to keep sufficient sheep to make a living on them alone.

Such changes also involve considerable expenditure, and it is not certain that wool prices will maintain for very long. In a year or two the position may be reversed.

However, I believe we can keep more sheep with profit without seriously affecting the acreage put into cereals, by more efficient rotations of crops than has been practised in the past.

Most producers in the Lower North District have a fairly efficient plant for the production of wheat, and this district is one of the best for wheat production. We should be able to grow wheat as cheaply as anywhere in Australia. Consequently it would be folly to scrap our plant at this time.

The question is: "How can we still lower costs of production to make ends meet?" There are two ways in which this can be still further reduced, and these are—

- (1) by increasing the yield per acre, and
- (2) by lowering the interest charges per acre.

The first can be raised by more efficient cultivation, improved varieties, and most important, by changing the rotation and bringing other crops into the rotation with wheat.

Interest charges—interest on working capital, land, and improvements—can only be reduced on the "per acre" basis by a longer crop rotation to eliminate a larger proportion of the bare fallow, portion of the farm which puts double rental or interest charges on to the wheat crop.

A study of the costs of wheat production as worked out at the Turretfield Demonstration Farm shows the following items in the cost of growing 19bush. on bare fallow for seasons 1929-32.

	Per Bushel.	
	s.	d.
Interest charges	1	2
Labor	1	0
Use of horses	0	8
Seed, super, and bags	0	10
Incidentals	0	3
Implements	0	2
Total	4	1

Professor Perkins works out the costs for various yields as follows:—30bush at 2s. 9d., 25bush. at 3s. 3d., 20bush. at 4s., 15bush. at 5s. 2d.

From this it will be seen that the effects of increasing the yield on the cost of production will require about 36 to 40bush. to meet all charges with wheat at its present price. It will be noticed that interest charges (or rent) is the highest charge, 1s. 2d. of which, with a 30bush. crop, means that all other costs come to only 1s. 7d. It is contended, therefore, that to reduce this high interest charge it is necessary to grow a greater variety of crops to absorb it. The following table shows returns at Booborowie and in the Wimmera over a number of years:—

Rotations.	Wheat Yield.		Oat or Barley Yield.	
	bush.	lbs.	bush.	lbs.
<i>Booborowie</i> —				
Fallow-wheat-oats	32	33	30	14
Fallow-wheat-pasture	32	33	—	—
Fallow-wheat-barley	30	35	17	45
Fallow-wheat	28	2	—	—
<i>Wimmera</i> —				
Fallow-wheat-oats	38	0	—	—
Fallow-wheat	34	0	—	—

These figures show that where a variety of crops is grown, higher yields are obtained, as well as reducing the acreage under fallow. With the fallow-wheat rotation, one-half of the farm only is in full production, whereas there are two-thirds in the others, so that the rent can be more evenly divided.

Improvements can be made to the pasture section of the rotation by sowing with oats or barley and grazing throughout the year. Part can be sown with barley or an early variety of oat, and the balance with a later variety so that early feed will be available, and the food of the other will last well into the summer with periodical grazing.

Annual grasses such as Wimmera Rye can also be sown alone or in a mixture and increase the feed value of the pasture, allowing more stock to be kept.

Where oats are sown in rotation they may be grazed as suggested, cut for hay or ensilage or harvested as grain. In districts of good rainfall, where the third crop in the rotation has been heavily fed off, a large proportion of the nitrogen taken out of the soil by the growing crop is returned and it is possible to make a 4-course rotation of it by following with another wheat crop before bare fallowing again. This can also be done when a good mixture of burr clover has grown with the oats, or if the oat crop is replaced by a pea crop.

When wheat is to follow pasture or another crop, there will be a limitation to the moisture and plant food available, so that it will be necessary to use wheats which will make rapid growth after sowing, and withstand droughty conditions.

Gluyas and Waratah are highly recommended for this purpose, while Nabawa and Sword have also done well in this way at Saddleworth. Last year a paddock was sown with oats and grazed until late September, the stock were then removed and a good crop of oats harvested for grain. There was a good stand of burr clover with the oats. The stubble was burnt and sown with Waratah wheat. A few half-acre plots of other varieties were tested in the same paddock and yielded as follows:—Waratah, 23½bush.; Nabawa, 23½bush.; Sword, 23bush.; Ghurka, 22½bush.; S.H.J., 20bush. S.H.J. is a West Australian variety—a cross between Florence and Early Jonathan, so should be a good milling wheat. This variety gained Champion Prize at the Adelaide Show last year. A farmer at Saddleworth grew a 9 bag crop of Florence on non-fallow this year, so it may be possible to obtain a payable return from good milling wheats when grown on stubble ground. Many of the good milling wheats are early maturing and command an extra 3d. per bushel.

The cost of growing wheat on stubble or ley ground is much cheaper than growing on bare fallow on the per acre basis as can be shown by again referring to Turretfield Farm Costing in the following table:—

Wheat.	On 1926-30.		Decrease Cost.
	Pea Stubbles (16bush.)	Fallow (19bush.)	
Per acre . . .	£3 7 7	£4 18 6	£1 10 11
Per bushel . .	0 4 3	0 5 2	0 0 11
Hay.	1923-31.		1922-32.
	Stubble Hay.	Fallow Hay.	
Per acre . . .	£3 12 3	£5 6 10	£1 14 7

This shows a saving of 30s. per acre, so that if a crop can be grown that will yield anything within 15bush. at 2s. per bush., it will give as good a net return as the fallow grown crop. These costs may seem a trifle high at the present time and my estimation is that a fallow crop can be grown at £3 10s. per acre and a stubble crop for £2 10s., so that with wheat at 2s. 6d., 28bush. on bare fallow and 20bush. on stubble should be grown to pay expenses. Two crop rotations which will help to reduce costs of production, enable the fertility of the soil to be maintained, and the stock carrying capacity increased are:—

1. Bare fallow-wheat-oats (sown with 2lbs. Wimmera Rye seed)-pasture.

The advantages of this 4-course rotation are to increase the pasture in quality and quantity, increase wheat and oat yields and keep down crop diseases. By leaving out for a year as a rye pasture, barley grass and silver grass would be kept in check, and as those grasses carry the take-all fungus, this would be kept in check. This rotation is similar to Rotation No. 10 as laid down at the Waite Research Institute which consists of bare fallow-wheat-oats-pasture. The pasture there is a Wimmera Rye grass stand sown the same year. This rotation gives the highest yields of wheat 41.2bush., the highest oats 66.6bush., and the highest in pasture taken as 41.2cwt. per acre of dry hay, of all the different rotations laid down at the Institute. Results are over the period 1926-32.

This rotation would be suitable for fairly large holdings, for only one-quarter of the farm would be under wheat. The Wimmera Rye grass—if sown with the oats—would not affect the crop to any extent, and sufficient seed would fall to give a good stand of grass for the next year.

The second rotation which would be more suitable for smaller farms of good soil and climatic conditions is as follows:—

2. Bare fallow-wheat-oats (hay)-peas-wheat-oats (grazed)-wheat.

With this rotation a maximum acreage is sown to wheat, 3/7ths of the area; and a minimum to bare fallow, 1/7th only; each paddock would be fallowed once in 7 years. With a farm of, say, 350 acres, if this was divided into 7 paddocks, the cropping would be as follows:—Wheat, 150 acres; oats for hay and grain, 50 acres; grazing crop (oats, barley, or grass mixture), 50 acres; peas, 50 acres; bare fallow, 50 acres. A rotation similar to this is now in operation on portion of our farm, and results of wheat yields on fallow and stubble are as follows:—Fallow, 32bush. at 2s. = 64s.—cost 70s., loss, 6s.; stubble, 25bush. at 2s. = 50s.—cost 50s. The peas part in the rotation could be replaced by bare fallow without changing the area under wheat and oats. Peas in rotation at the Waite Research Institute have yielded an average of 25bush. A good crop of wheat is fairly certain after a crop of peas, and similar returns can be obtained when sown after a heavily grazed crop, or a crop in which a large amount of burr clover has been present. If the roots have made such good growth and food is abundant so that the grazing crop can be harvested as hay or grain, it may be necessary to use a manure containing nitrogen if the rotation is to be followed through, otherwise a lack of this plant food will be felt. There is further need for experiment in this direction, for it is possible to show increased yields with sulphate of ammonia, but not sufficient to pay for the application.

Varieties of oats suitable for the rotations are *Calcutta Cape* and *Belar* (Sunrise × Algerian). These are mid-season, and can be fed off and recover well, lasting into the summer. They also make excellent hay.

Gidgee (White Ligowo × Algerian), the same cross as Lachlan and Guyra, is a good early hay and feed oat with a plump heavy grain. Bags averaged 150lbs. off the winnower this year.

Peas: Australia produces 800,000 out of the world's production of 30,000,000bush. Spain produces 7,000,000bush. or nine times that of Australia. White Brunswick have yielded up to 62bush. at the Waite Institute; they escape a lot of the grubs and command a higher price than Dunns.

Wimmera Rye grass grows well in a 15-20in. rainfall, seed is not expensive and a good stand can be established for 2s. per acre.

PASTURE IMPROVEMENT AND ROTATIONAL GRAZING.

[By J. B. STEPHENSON, Penwortham.]

This paper deals with the higher rainfall areas, and is my experience with grasses during the last five years on my property near Sevenhills. Where I have been using the common Subterranean Clover in the earlier districts the early type would apply equally as well.

It might be of interest to mention that the first man to realise the value of Subterranean Clover was Mr. A. W. Howard, of Blakiston.

Subterranean Clover is an annual which, on account of its characteristic of re-seeding by forcing the lower shoots into the ground, is quite permanent when once established. From this habit the clover derives its name. The plants grow very close together, the runners overlapping and crossing to a depth of several inches, forming a dense mat. The seeds germinate with the first good rains and die down about the end of November—to the middle of December in this district.

Subterranean Clover is a nitrogenous plant, and in the green state provides a succulent fodder of which all stock are very fond. If there are a few scattered patches in a paddock, it is always obvious which grass the stock prefer, as the clover will be nipped off short and the other grasses left. On account of its remarkable seed production it spreads with great rapidity, and with reasonable care and management of the paddocks, becomes firmly established and will last for years.

The ideal climate for Subterranean Clover is a temperate to cold one, providing there is an average rainfall of 20in. or over and that there is a reasonably wet spring. Given these conditions it will grow on practically any class of soil, and will grow where land is too cold and sour for other grasses to grow at all. It does well on poor ground, but makes wonderful growth on good land. The clover will grow without fertiliser and will spread, but only slowly. The fertiliser to which Subterranean Clover most readily responds is superphosphate, and the wonderful effect of this manure will more than repay the initial outlay involved in its use. Superphosphate may be sown with the seed, and then used to topdress the pasture.

The seed may be sown at any time from the first autumn rains until the end of July. The earlier seasonal conditions permit the seed being sown the better, as it gives the plants a better chance of establishing themselves before the seed is formed. As the plant is an annual, it is obvious that a good deposit of seed is essential the first season to ensure the continued spread of the plant. Often one hears the remark, "Yes, the clover did well the first year but died out," and the fault is generally not due to the plant, but to over-stocking before it has time to develop the seed supply. Also the complaint is sometimes made that it is very backward in the winter. That, again, is more often than not due to the fact that the stock prefer it to other grasses and give the natural grasses an unfair advantage.

There is one other point that should be of vital interest to producers. It has been proved in Victoria that Subterranean Clover will choke out St. John's Wort.

The first clover I sowed at Penwortham was half a paddock of 120 acres which had been cropped the year before. About the only foliage was stinkwort, which was doing remarkably well. I mixed the seed with 45 per cent. superphosphate and sowed at the rate of 4.5lbs. of second grade seed (equal to about 3lbs. of first grade) with 1cwt. superphosphate per acre. I used a disc drill with the hoes outside the discs, and the discs let into the ground. This was sown in the middle of June and soon showed a promising take. The sheep were taken off this paddock as soon as the flowers showed and kept off until the seed was formed and the plant had started to wilt. By that time enough had been buried underground to ensure a good germination next year. When sheep were turned into that paddock they nipped the clover off as close as any sheep can bite, and to anyone who was unused to the peculiar properties of the plant, it looked a failure. The next year it was topdressed with another 1cwt. of superphosphate and the growth was thick and was so well established that it did not need a spell for nearly so long a period as the first year. The next year it was not topdressed, and I now intend to topdress the paddocks in alternate years with 90lbs. of 45 per cent. superphosphate per acre. This, of course, wonderfully increases the carrying capacity of the land, and so ensures a lot more animal droppings, and it has been proved that sheep especially return nearly as much to the soil as they take out of improved pastures.

After a few years there is a tendency for worms to develop in sheep, and this must be guarded against. A good medicinal salt lick helps. About every two or three years harrow heavily or cultivate the paddocks to spread the manure and aerate the soil. This also applies to cattle grazing, as the growth of any grass is always strongest and more rank on or around animal droppings and is always the last eaten by the stock. Even distribution of manure ensures an even growth and sweeter pastures. A method I have found successful both for the spreading of cattle and sheep manure is to turn a set of harrows upside down and drag them over the ground. A better way is to use a good set of ordinary harrows with a heavy drag chain or four or five-plough chains fastened on each rear corner of the harrows to break the manure which the harrows allow to pass through untouched.

ESTABLISHING THE CROP.

The year the pasture is harrowed or cultivated it does not seem necessary to topdress. The sowing of pasture seeds with a cover crop is an excellent way of establishing a pasture, and I have had good results with clover and Wimmera Rye grass, by sowing with both wheat and oats and also to a lesser extent barley, but either wheat or oats are better for this purpose than barley. The land was ploughed, harrowed, and the wheat sown at the rate of 1½bush. per acre, 3lbs. clover, and 2lbs. of rye grass per acre were mixed with the super, which was put on at the rate of 1½cwt. of 45 per cent. per acre. Always leave the mixing of the grass seeds with the super until ready to be sown—some do the mixing in the drill box.

Do not plant the seed too deeply, and harrow the top after drilling to cover the wheat. The Subterranean Clover throws out exceptionally long heads when planted with a cover crop and seeds fairly well enough to give a good start for next year. The rye grass is very prolific. It was planted at the rate of 2lbs. per acre, and enough was blown over the tail of the harvester to seed the land thickly for the next year, and 20bush. were cleaned which collected in the screening box. That was off an 80 acre paddock. Of course, this crop cannot be cut with the binder, as it prevents the rye grass from seeding. The rye grass grew nearly as high as the wheat. Cutting the crop does not interfere with the clover plants.

Wimmera Rye grass is an annual, but is a very prolific seed plant. From one seed, 10 to 12 stems will grow with 20 to 40 seeds per stem. The seed is very light, and when it drops to the ground soon works underneath the straw and germinates with the first good rains. It is not advisable to burn the stubble, this destroys most of the rye grass seeds.

Perennial Rye grass is a coarser plant than the Wimmera. It grows best along the banks of creeks and where land is flooded in winter. It is rather rank for sheep but they readily eat the heads and flag. On the other hand, cattle do well and seem to relish this plant. Perennial rye grass makes excellent meadow hay, and mixed with any of the clovers makes an ideal grass hay for dairy cattle or winter feeding of ewes. The grass is easily established by discing the seed on to the land in autumn with about 1cwt. of super., and when once established is quite permanent, and has the additional advantage of sending out green shoots after rains in the drier periods of the year. The feed value of the perennial is not so high as that of Wimmera, and stock, if allowed to choose, show in no uncertain way which they prefer.

A pasture of pure clover has a tendency after a few years to become thinner and then after a year or so thicken up again. It will be noticed that as the clover thins out the other grasses increase and they in turn are choked out as the clover increases again. Any clover is a great producer of nitrogen and in time produces too much nitrogen and to a certain extent the ground is "clover sick." The other and poorer grasses which grow absorb the surplus nitrogen and allow the clover to spread again. The rye grasses are all nitrogen-absorbing plants and by experimenting it has been proved that clover and rye grass planted together keep a proper pasture balance, neither the rye nor the clover will predominate. Wimmera rye is best suited for sowing with clover for the drier parts of the property and Perennial for the flats and where water lies.

"PHALARIS TUBEROSA."

This is a perennial and is the best winter grass. It has an extensive root system, and once established is permanent. The surest way to start this grass is from roots, planting them about 3ft. apart the plant soon spreads on something the same principle as Couch grass.

Planting by Seed.—Be sure and obtain seed from guaranteed stock, as there are other types which are very inferior to the true plant. The Department of Agriculture will always advise where seed or roots can be obtained. The seed is planted at the rate of 3lbs. per acre on well prepared land with a liberal dressing of super. and as the seed is very fine, it is best sown on top of the ground and then lightly harrowed.

This grass is very susceptible to competition from other grasses in the first year of its growth, especially the rye grasses, but after it is well established, clover or rye may be sown with it. It also responds well to cultivating in the early winter, which seems to stimulate the growth.

Phalaris when properly established, produces an abundance of green fodder; the worst winter frost does not seem to affect it, and if allowed to grow, will make a good hay, which can be easily cut with the binder or loose mower. Stock seem to have to acquire a taste for this grass, but when once used to it seem to relish the fodder.

Subdivision.—Pasture improvement can have little permanent benefit unless subdivision of paddocks, topdressing with fertilisers, systematic harrowing, distribution of animal droppings and rotational grazing are adopted. The usual plan of having one or two large paddocks does not permit of any part of the farm being "rested" from time to time, but results in too much feed at one time and a shortage at another. This subdivision of the property permits parts of the holding to be rested from time

to time and so encourage the best features of the pasture. With smaller paddocks, the stock can be changed from one to another and short, fresh greenfeed ensured for a large part of the year. Grasses are highest in food value when about 3 to 4 in. high; long and rank grass is unpalatable to stock, besides lacking the feed value of the shorter grass. Another advantage of subdivision is that it lessens the waste caused by unnecessary tramping.

Another consideration in subdivision is the opportunity it affords for the control of the growth of the grasses, and an introduction of variety into the feed of stock. Variety of feed ensures a balanced ration, and the animal uses the maximum quantity of feed to the greatest advantage. It is also possible to devote different paddocks to different grass mixtures.

Subdivision and rotational grazing make it possible to considerably increase the carrying capacity of the farm, the small paddocks which are heavily stocked and rested in turn, do not grow much grass to waste. The amount of waste that occurs on a farm with few fences can only be measured by comparison with a similar area that is subdivided, and if regular topdressing is practised in conjunction with rotational grazing, the carrying capacity of the pastures may be doubled as compared with the farm with the few large paddocks.

To achieve this there is, of course, an original outlay and then periodical purchases of super., but when a pasture is well established, alternate autumn topdressings of 90lbs. to 1 cwt. of 45 per cent. super., and heavily harrowing or cultivating the land every third or fourth year, will give an ample reward for the time and money spent.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held at the Blackwood Experimental Orchard on February 28th, there being present Messrs. R. H. Martin (Vice Chairman), F. Coleman, P. J. Baily, S. Shepherd, A. L. McEwin, H. N. Wicks, G. Quinn (Chief Horticultural Instructor), R. Fowler (Manager Blackwood Orchard), and H. C. Pritchard (Secretary).

Apologies were received from Messrs. A. J. Cooke, J. W. Sandford, Professor A. J. Perkins, and Dr. A. E. V. Richardson.

New Branch.—Conditional approval was given to the formation of a Women's Branch at Wirrabara.

Life Members.—Messrs. E. H. and L. G. Huxtable, G. L. Bonython, H. S. Green, J. Waters, and V. V. Brown of the Borrika Branch were approved as Life Members of the Agricultural Bureau.

New Members.—The following names were added to the rolls of existing Branches:—Milang—G. Yelland; Belvidere—G. R. and A. K. Donaldson, R. H. Westley; Buchanan—E. O. and R. M. Pfitzner; Kelly—F. W. Russack, L. S. Beinke; Mount Gambier—A. L. Warren; Kybybolite Women's—Mrs. G. McInnes, Misses M. and K. Carracher, Mrs. G. Davidge; Wilkawatt Women's—Mrs. P. Thompson; Kybybolite—C. G., and John Boddington, R. Newlyn, D. Chapple; Owen—Arthur Pretty; Dudley—D. I. Telfer; Lameroo—Mr. Edwards, J. Hamilton, R. Morcom; Roseworthy—R. Freer, C. Forman; Quorn—L. Eckert; Block E.—W. B. Anderson, F. B. Gitsham; Mount Barker—C. Pope.

Present No. of members, 7,999; present No. of Branches, 336.

Several items were discussed in Committee.

EXPORT PIG COMPETITIONS.

“THE CHRONICLE” PRIZES, G. A. COOPER CUP, MONTHLY, AND SPECIAL PRIZES.

COMMITTEE DRAWS UP CONDITIONS.

[After the decision reached at a meeting of representatives of various interests in the pig industry on February 9, to hold monthly export pig competitions in connection with the Cooper Cup, “The Chronicle” prizes, and other monthly and special prizes, the Committee appointed by the Minister of Agriculture (Mr. Blesing,) consisting of the President, Stud Pig Breeders Society (Mr. H. J. Candy), the agricultural editor of “The Chronicle” (Mr. C. P. Butler), and the Chairman of the Meat Export Board (Mr. G. A. W. Pope), met and framed these conditions, which have been approved by the Minister. The competitions will begin on May 10, and will be held monthly for 12 months until April 30, 1935.]

Each entry shall comprise not less than five, and not more than eight pigs. In judging, the best five carcasses will be chosen by the judge. There will be no limit to the number of entries made by any one person.

Each pig shall weigh not less than 60lbs. or more than 160lbs. dressed frozen weight, and, for the purpose of judging, carcasses weighing between 60lbs. and 120lbs. shall be declared porkers, and from 121lbs. upwards baconers.

Entry forms may be obtained from the Government Produce Department, Light Square, Adelaide, the Department of Agriculture, Flinders Street, Adelaide, the Stud Pig Breeders’ Society, 23, Waymouth Street, Adelaide, any of the stock and station agents, and the Manager of the Port Lincoln Freezing Works.

GENERAL CONDITIONS.

Entries must be lodged with the General Manager of the Government Produce Department or the Manager of the Port Lincoln Freezing Works on or before the 10th day of the month in which the entrant desires to compete. It is provided, however, that entries for the May competition may be made from now on, and the pigs so entered may be slaughtered at any time between the date of entering and May 31.

After May 31 the pigs must be slaughtered in the month in which the entry is made. Slaughtering dates must be arranged by the entrants with the Produce Department, and the pigs must be delivered alive and free of charge at the department’s works, Port Adelaide, or Port Lincoln.

In the event of five carcasses in any entry not being suitable through rejection of all or part of the carcasses through any cause, the entry will not be permitted to take any part in the competition.

Exporters, breeders, fatteners, bacon curers, and producers generally, including those on Eyre’s Peninsula, may enter pigs for the G. A. Cooper Cup, and the Meat Export Board’s monthly prizes, also the special prizes presented by Messrs. Michie, White, and J. M. Wilson Pty., Ltd.

Pigs entered for the prizes to be presented by the proprietors of *The Chronicle* and the Stud Pig Breeders’ Society must be the product of boars of registered stock, and the breeding and age must be stated on the entry form. These pigs will be eligible for competition for all the prizes, including the Cooper Cup.

COOPER CUP.

The G. A. Cooper Cup competition will be confined to entrants competing in three or more of the 12 monthly competitions. The cup will be presented to the competitor gaining the best average of points over three monthly entries. Should any entrant compete in more than three monthly competitions, that person's best three entries will be accepted as the entries qualifying for the Cup competition.

The committee reserves the right to withhold the cup should the number of entries over the whole period be, in its opinion, insufficient to achieve the objective of the donor, which is to improve the quality and increase the quantity of the pigs exported from South Australia.

The pigs will be judged in Adelaide by an officer of the Government Produce Department for proportion of dead to live weight, for which a maximum of 20 points will be allowed, and for uniformity in weight for which a maximum of 10 points will be allowed.

The total judging points in Adelaide and London will be:—Proportion dead to live weight, 20; evenness of weight, 10; conformation, 15; suitability for trade, 35; shape of hams, 10; condition, 10; total, 100.

Should any dispute arise, the committee's decision shall be accepted as final.

The pigs will be sold and the proceeds, after deducting the usual charges, will be paid to the owners, and, when desired, the department will make advances on the pigs up to 75 per cent. of the estimated value.

There will be no entry fees.

METROPOLITAN AND EXPORT ABATTOIRS, ADELAIDE

MANUFACTURERS OF

Meat Meal for Pigs

Read Report of Trials made by PROF. PERKINS,
Journal of Agriculture, January and July, 1921.

Meat Meal for Poultry

For full information on above write to

The GENERAL MANAGER, Metropolitan and Export Abattoirs
Board, Box 578E, G.P.O., Adelaide.

ALSO MANUFACTURED—

Blood Manure

Bone Manure

SCHEDULE OF PRIZES.

The prizes will consist of:—

1. The G. A. Cooper Cup, valued at 30 guineas.

2. The Meat Export Board's prizes for each of the 12 months in which the competitions are held, consisting of:—(a) A rebate of 12s. a pig from the charges for treating, shipping, and selling the five first prize pigs (value £3 a month). (b) A rebate of 8s. a pig from the charges for treating, shipping, and selling the five second prize pigs (value £2 a month). Total value, £60.

3. Special Prizes:—

- (a) The Australian Stud Pig Breeders' Society prizes of £2 for first prize a month and £1 for second prize a month, for the months of May, June, and July, for pigs, the product of boars of registered stock.
- (b) The Michie White prize of £5 5s. for the best five baconers entered during the competitions and slaughtered at Port Adelaide.
- (c) The J. M. Wilson prize of £5 5s. for the best five porkers entered during the competitions and slaughtered at Port Adelaide.
- (d) The Wickham & Candy prize of a pedigreed Berkshire (Canadian) type boar for the best five porkers other than all white pigs.
- (e) The proprietors of *The Chronicle* prizes:—First £8, second £5, third £2, fourth £1 10s.; for the best pen of five porkers taken from a maximum entry of eight pigs.
- (f) The proprietors of *The Chronicle* prizes:—First £8, second £5, third £2, fourth £1 10s.; for the best pen of five baconers taken from a maximum entry of eight pigs.

Pigs competing for these two prizes, presented by *The Chronicle*, will be shown alive at the Royal Adelaide Show, subject to the concurrence of the Royal Agricultural and Horticultural Society, in accordance with the conditions laid down in the society's catalogue, including entry fees, and will be slaughtered in September.

- (g) The proprietors of *The Chronicle* prizes for pigs bred on Eyre's Peninsula:—First £5, second £2, third £1 10s.; for the best five porkers taken from a maximum of eight pigs.

The proprietors of *The Chronicle* prizes for pigs bred on Eyre's Peninsula:—First £5, second £2, third £1 10s.; for the best five baconers taken from a maximum of eight pigs.

The pigs for these special prizes are to be slaughtered in September and October at the Port Lincoln Freezing Works.

- (h) In addition, Mr. E. A. Wilcox will present a pedigree Large White boar to the winner of the porker class in the Eyre's Peninsula competition, and Mr. W. J. Aldridge will make a like presentation to the winner of the bacon class.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 4.—THE APPLE OF SODOM.

Solanum sodomaceum, L., var. *Hermannii*, Dunal.

In the writings of the ancient historians, Tacitus and Josephus, and of Strabo, mention is made of certain fruits, beautiful to the sight but turning to bitter ashes when eaten, which were to be found growing near the ancient cities of Sodom and Gomorrah on the shores of the Dead Sea. These "fruits"—in reality the galls formed on dwarf oak trees by a species of gall-forming insect—have given rise to the name "Sodom Apple" or "Dead Sea Apple" as a metaphorical expression to represent what excites high hopes or expectations, but ultimately produces bitter disappointment. The plant known botanically as *Solanum sodomaceum*, L., is called the Apple of Sodom because it bears an abundance of juicy yellow berries, an inch or more in diameter, which, so far from being edible, are intensely bitter and poisonous.

The plant in question is a native of Africa and the Mediterranean region. It is a common weed on vacant land in and around the suburbs of Adelaide, and occurs here and there along the roadsides throughout a good many parts of the State. It is a proclaimed weed both here and in Victoria, where it is very widely spread. It occurs also in Queensland, and to a less extent in New South Wales. In the last-named State it is to be found growing in greatest abundance actually in sand along the sea coast, and does not appear to penetrate inland, at least, not to such an extent as to justify its being regarded as a serious weed, being proclaimed only in the coastal municipalities of Botany and Stockton.

The Apple of Sodom is an irregularly branched, semi-shrubby perennial, bearing a mass of dark green sinuately lobed leaves, both stems and leaves being covered with prickles. The flowers, which are purple or purplish-white in color, resemble those of a potato plant, and develop later into the berries, which are at first green and white, but turn pale yellow when ripe. Well fed stock refuse to touch the plants, the prickles evidently serving, in this case, the very useful purpose of deterring animals from eating the leaves and fruits.

Botanical Name.—*Solanum* was the Latin name for the Black Nightshade, *S. nigrum*, L., and was derived, probably, from the word *solari* to solace or comfort, in allusion to the reputed sedative properties of that species. The species name *sodomaceum*, as already explained, is on account of the disappointing qualities of the attractive-looking fruits. The local form belongs to the variety *Hermannii*, which occurs in Africa and in southern Italy. It differs from most Mediterranean forms in having the branches and both surfaces of the leaves sprinkled with minute star-shaped hairs.

The Family Solanaceae.—In common with other species of *Solanum*, the Apple of Sodom belongs to the *Solanaceae* or Nightshade family, which comprises some 1,500-1,800 species of plants native to tropical and temperate regions. Among these are such economically important members as the potato (*Solanum tuberosum*, L.), the egg-plant (*S. Melongena*, L.), the tomato (*Lycopersicum esculentum*, Mill.), tobacco (*Nicotiana Tabacum*, L.), red or Cayenne pepper and chillies (*Capsicum annuum*, L.), and the Cape Gooseberry (*Physalis peruviana*, L.). Many plants belonging to the family contain poisonous alkaloids, and of these the Deadly Nightshade (*Atropa Belladonna*, L.), the Thorn Apple (*Datura Stramonium*, L.), and Black Henbane (*Hyoscyamus niger*, L.), are used in medicine and yield the drugs Belladonna, Stramonium, and Hyoscyamus, respectively. In addition to species of *Solanum*, certain solanaceous plants are more or less common in this

Photograph of plant of Apple of Sodom, showing general habit. See colored plate opposite.

APPLE OF SODOM

State as naturalised weeds, e.g., Tobacco Tree (*Nicotiana glauca*, Grah.), African Box-thorn (*Lycium ferocissimum*, Miers.), Thorn Apple or Mad Apple (*Datura Stramonium*, L., *D. tatula*, L., *D. Metel*, L., and possibly also *D. ferox*, L.). The same family includes such garden favorites as *Cestrum*, *Petunia*, *Salpiglossis*, and *Schizanthus*.

In addition to the frequent presence of poisonous alkaloids, such as atropine, nicotine, solanine, daturine, etc., members of the family have certain structural characters in common. The flowers are more or less radially symmetrical; there is a persistent five-lobed calyx, a corolla of five petals joined to form a tube of varying length, five stamens arising from the corolla, and a superior pistil, situated upon a hypogynous disc and composed of two united and obliquely placed carpels, with an ovary containing usually numerous ovules attached to axile placentas. The ovary subsequently develops into a fruit which may be dry and capsular, or succulent and berry-like. The seeds are usually small and numerous, and contain endosperm.

Many *Solanaceae* show peculiarities in the position and arrangement of leaves and flowering branches, due to adnation or coalescence between the primordia of neighboring parts. The prevailing leaf arrangement is alternate, and this is usually found in the vegetative parts; but, on the flowering branches, the leaves sometimes arise in pairs, due to the failure of certain of the leaf rudiments to separate from the parent stems, except at levels considerably above their true points of origin.

Another and very general character of the family is the presence, in the stems, of internal food-conducting paths. The stem of a plant, being an intermediary zone between roots and leaves, is concerned with the conduction, not only of water and minerals to the leaves, but also of elaborated foods from the leaves to the roots, which, being living, necessarily require to be supplied with these materials. This conduction takes place through the inner part of the bark, just outside the wood, and is confined in most plants to this region of the stem. The method of ring-barking aims at killing a tree indirectly by depriving the roots of their food supply, and is usually effective so long as suckers are not allowed to develop below the level of the ring. But ring-barking would not kill a solanaceous plant, because the roots would continue to receive a supply of sugars and proteins via the internal conducting paths, which are situated on the inner side of the wood.

The Genus Solanum.—More than half the total number of solanaceous plants belong to the genus *Solanum*, which comprises upwards of 900 species of varying habit, and is represented in most parts of the world. About 50 species are present in Australia. The most important economically is the potato (*S. tuberosum*, L.), a native of Chile and Peru, and introduced by the Spaniards into Europe between 1560 and 1570. It was brought to England in 1584 by Raleigh from Virginia, where it had probably been introduced by the Spaniards from South America. Another important economic species, the Egg-plant (*S. Melongena*, L.), is probably a native of tropical Asia. Of the 19 species in South Australia, *S. sodomacum*, L., and *S. rostratum*, Dun., are introduced weeds, the latter—called Buffalo Burr—being a native of Mexico and western U.S.A. Of the remaining species, all of which are native, the commonest is the Black Nightshade (*S. nigrum*, L.), an almost cosmopolitan weed in this State, often wrongly called Deadly Nightshade, a name which really belongs to a much more poisonous plant *Atropa Belladonna*, L., which does not grow in South Australia except, perhaps, in a few private gardens. *S. nigrum* is a herbaceous annual or biennial, without prickles, and with small white flowers and globular berries of a black or dark-purple color. It is somewhat poisonous. Another native *Solanum* is the Kangaroo Apple (*S. aviculare*, Forst.f.), which is sometimes confused with the

Apple of Sodom, but differs in its leaf form, as well as in being devoid of spines or prickles. The orange-colored berries of this species are smaller than those of *S. sodomaeum*, and are said to be edible.

Botanically the *Solanums* are characterised by their symmetrical flowers with rotate corolla, the cone-like arrangement of the five stamens, which are placed close together and surround the slender protruding style, and which shed their pollen through terminal pores and not by the lengthwise splitting of the anthers; also by the berry type of fruit with usually numerous small flattened albuminous seeds, each with a curved embryo inside.

Description of S. sodomaeum, var. Hermannii.—A semi-shrubby plant of more or less spreading habit, from 18 in. to several feet in height. Branches covered with stellate hairs, and armed with scattered, straight, awl-shaped, pungent spines $\frac{1}{4}$ to $\frac{1}{2}$ in. long. Leaves petiolate, mostly about $3\frac{1}{2}$ in. long and $2\frac{1}{2}$ in. wide, deeply and sinuately lobed, with scattered hairs on both surfaces, the petioles and nerves spiny, the lobes rounded. Flowers solitary or few in short cymes; calyx bell-shaped, densely (or sometimes sparingly) spiny outside, stellate-hairy, the lobes linear-lanceolate and acute, slightly scarious on the margins, closing over the young fruit, becoming reflexed when the fruit is mature; corolla violet, plicate, 1 in. in diameter, the lobes broadly ovate, cuspidate, stellate-pubescent outside; stamens shorter than the corolla, the anthers oblong with two small apical pores; ovary globose, glabrous, with a nearly straight style thickened at the base and terminating in an almost hemispherical stigma. Fruit depressed-globular, $1\frac{1}{2}$ in. in diameter, at first green variegated with white, finally pale yellow.

Period of flowering: October to April.

Means of Spreading.—The Apple of Sodom is spread by seed. Probably wind and rain are the chief agents of dispersal, for, unlike its near relative the African Boxthorn, the berries of which are eagerly sought after by birds, this plant is left severely alone by most animals. The berries are left to rot on the parent bushes, any full grown specimen of which will show numbers of the dried and shrivelled remains of the fruits of the previous year. These eventually become detached, and are then doubtless carried by rain or wind, the contained seeds germinating at some distance from the parent plants.

Properties.—The poisonous nature of the berries, which are stated to have caused the death of children, is due to the contained alkaloid, *solanine*, present in varying amounts in many species of the genus *Solanum*. This substance is abundantly present in the potato plant, not so much in the tubers, but in the green parts, especially in the young sprouts, and fatal poisoning has been known to follow the ingestion of potato shoots. The normal potato tuber contains very little of this alkaloid, about 0.04 gram per kilogram of unpeeled tuber; but some young potatoes have been found to contain 0.23 gram, and some newly budded from seed as much as 0.58 gram. Epidemics of solanine poisoning have occurred in military barrack-rooms as a result of eating potatoes with an abnormally high solanine content, and similar outbreaks have been known to take place among civil populations. In Glasgow in 1917, 61 persons were poisoned as a result of eating potatoes which were subsequently found, on analysis, to contain five or six times the amount of solanine of normal potatoes. The same alkaloid has been responsible for cases of poisoning due to eating the berries of *S. nigrum* and *S. dulcamara*. Solanine is a glucosidal alkaloid, that is, it is readily hydrolysed to form a sugar and another alkaloid *solanidine*, which retains the poisonous properties of the parent substance. Taken internally it acts as an irritant, causing acute gastro-enteritis, and producing such symptoms as headache, severe colic, hot skin, fever, rapid pulse, vomiting in some cases, in others nausea only, diarrhoea, great weakness, and depression. It also acts upon the general nervous system, though somewhat irregularly, causing giddiness, dilatation of the pupils, and, in severe cases, paralysis of respiration, coma, and death. The latter effects may be due to the presence of small amounts of other substances, such as atropine and other tropines. Further—

more, there appear to be slight differences in the physical and chemical properties of solanine obtained from different sources. Thus Willimott found that the solanine—distinguished as *solanine-S*—isolated from *S. sodomacum* had a bitter taste and an irritating action on the throat, not observed in other samples; also that it gave somewhat different color reactions.

Eradication.—The Apple of Sodom is a perennial plant, but is not difficult to get rid of, once its eradication is conscientiously undertaken. It does not spread as rapidly as Boxthorn, nor does it form impenetrable thickets, the individual plants being usually well spaced out on the ground occupied. Repeated cutting will soon exhaust it, but it is better, if such is at all practicable, to dig out or pull up the plants with the roots, and to burn them in heaps as soon as they are sufficiently dry. On arable land it is easily kept under by cultivation.

(The writer desires to express thanks to Dr. R. S. Rogers for allowing him to consult his private library.)

STATE OF SOUTH AUSTRALIA.

EXPORTS OF EGGS AND EGG PULP, JULY-DECEMBER, 1933 AND 1932.

By W. L. JOHNSTON (Government Statist).

Compiled by the Government Statist from returns collected direct from Merchants.

GRAND TOTAL EXPORTS.

Quantity.—Eggs in shell and in pulp in terms of eggs in shell—July-December, 1933, 5,600,000 dozen; 1932, 5,000,000 dozen.

Value.—July-December, 1933, £263,819; 1932, £245,228, increase £18,591. The interstate trade increased from £33,971 to £52,474, and the trade with oversea countries was just slightly ahead of the 1932 level, £211,345 (£211,257).

The following are the details of exports, July-December, 1933 and 1932 :—

State.	Eggs in Shell.		Egg Pulp.		Total Value.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 3 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 5 Test.—Morning—1 $\frac{1}{2}$ ozs. wheat per bird.

Evening—1 $\frac{1}{2}$ ozs. wheat per bird.

Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to February 28th, 1934.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

No. of Test.	No. Eggs Laid April 1st to January 31st.	No. Eggs Laid Month February.	Total Eggs Laid April 1st to February 28th.
No. 1	6,318	610	6,928
No. 2	5,957	575	6,532
No. 3	5,408	565	5,973
No. 4	6,304	840	7,144
No. 5	2,857	295	3,152

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

MEN'S BRANCHES. SOUTH-EASTERN DISTRICT.

KYBYBOLITE.

December 15th.—Attendance, 32.

FARM MACHINERY.—Mr. A. R. Shepherd read the following paper:—"The most important points in the care of farm machinery are protection, lubrication, careful handling, adjustments, and an occasional coat of paint. All implements which contain woodwork of any description should be afforded protection. Quite a number of machines are only used one month in the year and then left under a tree for the remaining 11 months. Consequently they are rotted and rusted long before they have a chance of wearing out. This necessitates a large machinery shed, preferably constructed of galvanized iron. A straw shed continually needs fresh straw to keep it waterproof. The risk from fire when using straw is enormous, and it also makes a comfortable home for the sparrows. An occasional coat of paint or oil will greatly add to the life of implements, but if machines are cleaned and put away under cover as soon as their jobs are completed they will retain their original coat of paint for years and painting will become almost unnecessary. If all wooden wheels on wagons, carts, drays, and buggies are soaked in oil once a year, it will not only dispense with the trouble and cost of cutting and shutting tyres, but will preserve the wood indefinitely. The lives of boxes and axles of ploughs can be prolonged by making a good leather or tin guard around them, or a super bag is quite satisfactory. Never put a drill or combine in the shed before first cleaning out the super hopper, and see that the tubes hang straight, or take them right off. Lubrication: Only the very best oil and grease should be used. Before starting a machine that has been idle for some time, all oil cups should be thoroughly cleaned, wicks replaced in their right positions, and broken ones renewed. The cups can then be filled with kerosene, this will remove all gummy oil from the bearings and give fresh oil a good lead. All machinery will at some period need some small adjustments, and these should be done as soon as they become necessary and not left until some damage has been done. After working a new machine for a day or two, it should be examined thoroughly to see if all bolts are tight, and none are broken, as it is the first few days that they are likely to work loose. Thereafter, if the operator keeps his eyes open when oiling, he will notice anything that is amiss; it is the 'stitch in time that often saves nine.' The preparation of all harvest machines should be done a week or so before they are needed, then when the crop is ready one can get straight at it with no waste of time. The binder, header, and harvester, having many working parts, need special attention—all chains and gears need adjusting occasionally. A gear meshed loosely will wear rapidly and be very noisy, one meshed too tightly will give heavy running and throw undue strain on the bearings. In these localities where very little sand is encountered, frequent applications of old sump or gear case oil to crown wheels, pinions, and gears will be found of great benefit. The mower—which is now becoming popular in this district—needs more attention than the average farmer is led to believe. Ledger plates should

be renewed as soon as the edge becomes dull or broken. The steel knife supports on finger bar should be adjusted as they wear to keep the knife in its right position. The knife clips will also need binding, thus ensuring that the knife will be kept down on ledgers. The knife should be sharpened at least twice a day, and if these points are watched, there will be not only a great saving on working parts, but also on horse flesh. To get the best out of the farm engine there are quite a number of points to watch. One often sees an engine belching smoke like a railway locomotive, consequently it is probably wasting as much fuel as it is converting into power. The most likely causes for this are unsuitable fuel for that particular engine, engine too cold or wrongly adjusted. It is a good plan to try a variety of brands of fuel, it will be soon noticed which is giving the best results. Speaking generally, more harm is done to engines through running them at too low a temperature than results from overheating. The reason for this is immediately the vaporised moisture in the air taken in strikes the cold cylinder wall it condenses, thus forming a film of water. This water on account of it being a poor lubricator causes the piston and cylinder to wear rapidly. Therefore, to eliminate this, engines should be worked very near to boiling point and some of the smaller types give best results while working at boiling point. There are many farmers, regardless of repeated warnings given by manufacturers, using heavy bearing oil for lubricating the cylinder. A lot of good will result from giving the valves a grinding occasionally, this being done similar to those of a motor car. The ignition being of vital importance, magneto and spark plugs should not be neglected, although good makes need little attention. It is now being found with the high compression used for the charcoal gas producer on tractors and trucks that cheap magnetos are worthless. So it will be seen the higher the compression the more efficient the ignition must be. If an engine is prone to pre-ignition on heavy loads it can sometimes be stopped by making the mixture a little richer. The most essential item for cutting expenses of repairs is a blacksmith shop, and no farm is up to date without one. One great advantage is that many a wet day can be very profitably spent. Quite a useful outfit can be purchased from £20 to £25. No expert knowledge is needed to effect a number of repairs which otherwise would be tied with a piece of wire, only to break again at some inconvenient time. To say nothing of the countless other jobs such as sharpening tools, making swings, gate hinges, hooks, and shoeing, that can be accomplished by any handy man. If these things are made from old scrap iron, which can be easily obtained, their costs would be practically nil." At the conclusion of the paper Mr. Shepherd gave some interesting hints on grinding combs and cutters for a shearing machine. (Secretary, A. Shepherd.)

January 30th.—Attendance, 15.

The meeting took the form of a Question Box. What was the cause of fermentation in tomato sauce? *Ans.*: Nearly always faulty vinegar. Remedy—Empty sauce into large basin and add a little baking soda (1 teaspoon to quantity contained in 6 bottles). basin and add a little baking soda (1 teaspoon to quantity contained in 6 bottles). Stand for a while and then boil again. How to deal with borers in sideboards? *Ans.*: Spray with mixture of turpentine and epsom salts. How to remove grass stains from clothes? *Ans.*: Rub with eucalyptus, then wash. How to overcome the difficulty of buttermaking in summer? *Ans.*: Hang cream out in air overnight in wet calico bag. (Secretary, Mrs. W. Kekwick.)

MOUNT GAMBIER (Average annual rainfall, 30.55in.).

January 12th.—Attendance, 9.

IMPORTANCE OF THE DAIRYING INDUSTRY IN THE SOUTH-EAST.—Mr. R. W. Grancy delivered the following address:—"The dairying industry in the South-East is a major industry, yet a great number of people insist on saying that their cows are a sideline. The man at the factory regards this as a feeble excuse for lack of care in the delivery of milk. Suppliers fail to realise the importance of this branch of their product. They pay more attention to their fences, land, and animals. But in the milking process and carriage of the milk to the factory haste seems to be the chief factor, and cleanliness suffers.

Cleanliness Important.—It is not possible for every dairyman to build perfectly clean milking yards, because of the expense involved, but they can, with very little expense, ensure these points, which are easily carried out:—(1) That their hands are clean before going to milk; (2) that the udders and teats are washed before milking; (3) that each bucket and can has been thoroughly cleansed since the last time it was used. This point is the greatest cause of trouble to the supplier and to the factory. In some districts milk obtained from cows with milking machines is not accepted at the factory because it has always been difficult to determine how clean these machines

really are. When milking, all milk should be carefully strained, and cans removed from the cowyard and any odour. Aerating is very beneficial if it is done in a clean place away from smells and dust—it allows the food flavor to escape, and, by cooling, the growth of germs is retarded. Aerating in an impure atmosphere does more harm than good. It is remarkable how very few farmers cool their milk. Cooling can be done by placing the cans in cold water, but it must be remembered that the water must be changed as it becomes warm from the heat of the milk. As in all branches of dairying, cleanliness is of the greatest importance. Sufficient care is not devoted to the raw material by those who milk the cows and handle the milk before it is delivered into the factory, and it is at this stage that it is more liable to contamination from careless and uncleanly habits.

Conditions at the Farm.—While conditions of manufacture have been brought to a reasonably good standard, the general conditions on many dairy farms leave much to be desired. The conditions there are far from ideal, and without suggesting

improved milking yards and bails at a time when low prices are the rule, a general improvement in handling the product and associated conditions could be effected in most cases with no extra expense and with very little extra time.

Dairy Regulations.—Since the Dairying Regulations have come into force in the South-East it has been compulsory to grade all milk brought to the factory. This, no doubt, has to be done by the man that holds the grading certificate. The man grading relies on taste and smell; failing this he has his acidimeter, which science has brought forward. These have been used in factories continuously of latter years. The acidimeter is not new to dairying, as many years ago Mr. John Davidson, a great cheesemaker in early days, brought it from New Zealand and used it at a factory near Millicent. Many taints and smells develop in milk as a result of people carting whey in milkeans and leaving it in them until they want them for the evening's milk. This practice, combined with a hurried wash at the last minute, becomes a serious menace to good quality. The regulations state that no whey shall be removed from any factory in cans used for milk unless scalded to 180 degrees and held at same for 30 minutes. This scalding of whey seems impossible, and the sooner we leave off putting whey in the cans the better for all concerned. The observance of regulations by persons who are usually clean in regard to handling milk products presents practically no difficulty at all, but these regulations are really formed with the intention of straightening up the careless or negligent supplier. Strict grading of milk and its products is an absolute necessity nowadays if we wish our product to maintain a good reputation not only on the local market, but overseas as well. The cheesemaker, no matter how good he may be, has not yet been born who can make a satisfactory article from inferior quality milk. Unfortunately, the careful supplier in the past has had to suffer to some extent as a result of the careless one. One or two faulty milks have frequently ruined a whole vat of reasonably good quality milk, and the reduced price which is realised for the finished product affects all patrons in a like manner. If the regulations provide the means of improving some, if not all, of the low quality milk to a higher level they have been well justified." (Secretary, G. Gurry.)

UPPER NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

APPILA (Average annual rainfall, 14.66in.).

February 2nd.—Attendance, 14.

HARVEST REPORTS.—Members reported an erratic germination. Other than a little damage by smut, no diseases were reported. Although hot winds in October made some reduction in yields, in many instances crops turned out much better than was anticipated. The following yields were reported:—Nabawa, 18bush.; Ranec, 18bush.; Turvie, 18bush.; Sultan, 16bush.; Sepoy, 15bush.; Leather Head, Currawa, 15bush.; Free Gallipoli, Gallipoli, Dan, Canaan, 14bush.; Noongar, 13bush.; Waratah, 16bush.; Nawab, 12bush.; Teagle, 14bush.; Daphne, 9bush.; Caliph, 8bush.; Sword, 8bush.; oats, 36bush. and 15bush.; barley, 19bush. and 9bush. (Secretary, E. Wurst.)

WILMINGTON (Average annual rainfall, 17.43in.).

February 13th.—Attendance, 17.

HARVEST REPORTS.—The two outstanding crops in the district were those of Messrs. E. H. Hampel and M. H. Modystach. Mr. Hampel's crop was sown on fallow with 60lbs. seed with 80-90lbs. super, and the seed dry pickled with 2ozs. to the bushel. No disease or haydie present; a little flag-smut in Onas and Gallipoli. Yields:

Ranee 26bush.; Onas, Currawa, and Gallipoli 24.25bush. Mr. Modystach: Sown on fallow and 65lbs. seed, 60lbs. super. Ranee 21bush., Joffre 18bush., Federation 21bush., and Free Gallipoli 27bush. Mr. J. J. Modystach: Ranee 21bush., Ford 18bush., sown on fallow, 1bush. seed per acre and 30lbs. super mixed with 30lbs. stable manure. Other crops not in favored areas were poorer in yields owing to the unfavorable growing period, mainly through lack of rain. The most outstanding wheat was Ranee, which did well in every instance. Gallipoli made a favorable impression by yielding better than it looked, although only a small area is yet sown with this variety. In many instances Nabawa was not favorable, and a few farmers are discarding this variety. All late sown crops were practically failures. Mr. E. L. Orchard (District Instructor), in a summary of the reports, mentioned that Ranee was the most outstanding wheat in the north, closely followed by Nabawa. He advocated the sowing of Ghurka where Nabawa was unsatisfactory, as this variety was closely related to Ranee. The Hon. Secretary (Mr. C. Cole) read a paper, "Aberdeen-Angus Cattle."

NOW BOOKING ORDERS FOR SPRING, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

**DELIVERY.—CHICKS—July to September.
EGGS—July to September.**

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

MIDDLE-NORTH DISTRICT.**(PETERBOROUGH TO FARRELL'S FLAT.)**

BEETALOO VALLEY (Average annual rainfall, 23.50in.).

Attendance, 9.

HARVEST REPORTS.—Mr. J. Fradd reported that wheat yielded better than the previous year; Ranee 11 bags, and Nabawa sown on stubble land 5 bags per acre. Mr. P. Ourtin received 11 bags per acre from Sword, 8 bags Nabawa, and 7 bags from Currawa. Hay cut was heavy and prices were good for the light wool clip. The citrus crop was light with low prices. Mr. W. Semmens' average was low: Daphne 5 bags, Currawa 4, Nabawa 3½, and Florence 4. Mr. B. Giddings received 6 bags of Brunswick peas per acre from a crop slightly affected with grubs. Hay cut 30cwts. Citrus crop light. Mr. J. Ryan's citrus crop was light, tomatoes good, and hay cut fair. Mr. J. Halse's wheat crop averaged 7 to 8 bags; Sword 10, Currawa 8, and Nabawa 6 bags per acre. The wool clip was light, but prices compensated with a 19d. average. Citrus very light. Mr. S. Jones received a 30cwts. hay cut from Waratah and 6½ bag yield from Currawa. Apples fair, citrus light, and prices low. The Secretary reports there is every prospect of a good citrus crop for next season, although the season is rather dry at present. Apples and pears are light owing to frosts. (Secretary, B. W. Giddings.)

BLYTH (Average annual rainfall, 16.77in.).

January 26th.—Attendance, 19.

DO SIDELINES PAY?—Paper read by Mr. W. Brereton:—"I am of the opinion that sidelines are a profitable avenue of farm activities. The figures quoted are the average prices of the various products over the last few years. The best sidelines are sheep, cows, fowls, and pigs. *Sheep.*—I have worked this out for a farm to carry 120 for the breeding of fat lambs for the market with an 80 per cent. lambing (96 lambs). All of these may not be fit for market, and allowing 16 to be culled out and 30 other sheep for filling, the meat should pay the interest and paddocking of the rest:—120 ewes, cutting 10lbs. of wool at 8d. per lb., £40; 80 lambs, averaging 12s. each, £48; 46 skins at 4s. each, £9 4s.=£97 4s. *Cows.*—A farmer can keep six or eight cows, so I have worked this out on the larger number. It takes no more to feed a good cow than a poor one, and a cow that does not give 300lbs. butterfat at maturity is not worth keeping. There will be seven calves a year from this number of cows, and five of these could be sent to market and the other two kept to place in the herd if it is decided to cull one or two for age at a later period:—8 cows produce 2,400lbs. butterfat at 9d. per lb., £90; 5 calves at 35s., £8 15s.=£98 15s. Eight cows would consume 16 tons of chaff at £2 per ton, £32; 3 tons bran at £5, £15; 2 bags salt at 6s., 12s.; bonemeal and super, £1=£48 12s.; total=£48 12s.; balance=£50 3s. *Fowls.*—Fowls running on free range do not require so much feed as those kept in houses. Two hundred fowls would eat about 75 bags of wheat in a year and lay about 15 dozen eggs per bird; 200 hens would lay 3,000 dozen eggs, at 6d. per dozen, £75; 75 bags wheat at cost of production, 10s. bag, £37=£37 10s. *Pigs.*—It takes three bags of wheat to produce a handy-weight bacon pig of about 140lbs, and a farmer should be able to put 20 pigs through his hands in a year with the separated milk and plenty of water, buying them as weaners and selling as baconers:—20 baconers at £3 10s. each, £70; against 20 pigs bought as weaners at 12s. 6d., £12 10s.; 60 bags wheat at 10s., £30=£42 10s.; balance=£27 10s. These figures added together show:—Sheep, £97 4s.; cows, £50 3s.; fowls, £37 10s.; pigs, £27 10s.; a total of £212 7s." Members considered that the writer had over-estimated the income from sidelines. Mr. Stuart delivered an address on "The History of the Merino Sheep." (Secretary, R. Eime.)

WIRRABARA (Average annual rainfall, 19.34in.).

August 12th.—Attendance, 14.

MANAGEMENT OF HORSES.—Paper read by Mr. A. Hill.—“Working horses need good care, plenty of feed and water, and well-fitting harness. Collars should fit them comfortably, and the hames fit the collar. I prefer the short hames with a strap at the top. The long hames tend to spoil the collar by pushing it out of shape and pinching the top of the horse’s neck. If the collar is pulled too narrow in the top, immerse it in water until it is properly soaked, and then obtain a piece of board the right width and put it in the top of the collar and buckle it up and leave the collar until it is dry. It will then be the right shape. If a horse has a sore shoulder, procure a fresh sheep skin—just shorn, if possible, is best—no matter how fat it is, line the collar with it, with the flesh side to the horse’s shoulder, and that in many cases will cure bad sores. When working horses they should be in the yard by sundown, or they will not keep their condition. Do not over-drive or overload them. See that trace chains are both the same length, and swings and spreaders the right width, and there will be very little trouble with sore shoulders.” (Secretary, F. Borgas.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

NANTAWARRA (Average annual rainfall, 15in.).

January 25th.—Attendance, 9.

LUCERNE.—Mr. W. J. Hamdorf read an article from the *Journal*, "Establishing Lucerne in the Bute District," and spoke of his experience of lucerne on sand, carrying three times more stock to the acre than natural pasture. It made good use of many acres of drift sand that was useless for feed previously. Mr. Hamdorf said Wimmera rye grass was a good green fodder, was no trouble in the cereal crop, and kept green much longer than any natural pasture. Mr. E. V. Hamdorf thought lucerne a wonderful feed plant; 2lbs. of seed to the acre could be sown. He had tried 4lbs. this year with wonderful results. Wimmera rye grass was a splendid winter feed, and made enough growth to choke out barley grass, and was a remarkable fodder for fat lamb raising. Mr. Palfrey thought Italian rye grass made better growth and would be better than Wimmera rye grass. Mr. G. Belling spoke of livestock activities coming more into prominence. Mr. Nicholls thought the introduction of grasses a wonderful asset, and mentioned Mitchell grass as being good for fodder. Mr. W. Starkey introduced a discussion on the care and treatment of the draught stallion. (Secretary, S. Herbert.)

SUTHERLANDS (Average annual rainfall, 10.88in.).

December 7th.—Attendance, 14.

DAIRYING IN THE SUTHERLANDS DISTRICT.—Paper presented by Mr. J. Schroeder:—"It is necessary to find out as soon as possible which are the good cows and which are the boarders, because there is little enough in good cows and less in bad ones. This can be done by weighing the milk from each cow and testing it, for which purpose a Babcock tester is necessary. Failing that, the factory manager will do the testing and the Department of Agriculture will also test the herds for a small fee. Testing should be done at, say, intervals of three to four weeks, to ascertain which cows should be excluded from the herd. In districts where it has been necessary to economise an attempt should be made to build up the herd with stock that will produce well.

Milking Cows.—Before commencing to milk the milkers should always wash their hands, and to avoid the fine dust from entering the milk, the cow's teats should be washed, as this dirt or fine dust enters the bucket and dissolves in the milk and no strainer will catch it.

Feeding Cows.—It is impossible to get good returns from the best of cows unless given a ration from which to produce milk and butterfat. It is most unfortunate for farmers of this district who are so often handicapped with failing seasons, but if possible in good seasons oats could be sown so that cows could be fed on a little crushed oats and bran. It is advisable to find out the most suitable feed, because some cows can consume more concentrates than others without hurting them. To assist the cows in dry years, a drench should be given once every month.

A large plot of lucerne would require too much water and prove too costly, but those farmers who have the water would be amply rewarded if they grew a small plot of lucerne, so that a handful or so a day could be given the cows. It is a common occurrence for cows to chew bones and rags, which signifies that there is something lacking from their food. To correct this habit I suggest a salt lick, or mineral added to the feed.

Young heifers should be encouraged to become accustomed to handling. This helps to break them in for when they have to be milked. If possible, milk without the use of the bail; the cows are more contented and can be approached anywhere in the paddock. Teach each cow to know its place at feeding time, because the 'bosses' soon devour their rations and then keep the others away from theirs.

Calving.—A week or so prior to calving it is a good plan to treat the udder of the cow with a little lard; it is a simple remedy and cheap, but will often help to prevent a lot of trouble. Continue this for several days after calving. A cow that has calved should be milked three times a day until her milk is fit for use." (Secretary, E. Schiller.)

YORKE PENINSULA DISTRICT.

BOOR'S PLAINS.

February 4th.—Attendance, 14.

HARVEST REPORTS.—Mr. R. Yelland gave the following report:—"The season has been below an average rainfall for the district, and the lack of winter rains, together with the dry finish, thinned the crops considerably, and some crops suffered with the late frosts. Despite these factors, it is pleasing to see the amount of wheat that has been reaped. Good fallow and the right time of sowing, &c., together with suitable wheats are points in favor of the grower. The most popular wheat was Sword; it has done well in practically every district. Barley was not up to standard, but if one had a good sample it was a better proposition than wheat. Seventy acres of Sword on fallow yielded 508 bags; a fine crop until damaged by the hot winds. It is inclined to be a little delicate—like Ford—on the poorer class of ground. One hundred and fifty acres of Nabawa and Daphne on fallow returned 1,076 bags. Daphne was the better crop. The best of it went eight bags, but it had the better end of the paddock. One hundred acres of Rance on fallow yielded 724 bags. One hundred and fifty acres of Waratah on fallow returned 884 bags. This crop was severely frostbitten. Sixty

WESTERN DISTRICT.

GOODE (Average annual rainfall, 10.16in.).

November 1st.—Attendance, 14.

CARE OF FARM HORSES.—Paper read by Mr. B. A. Linke:—"There has been a considerable disregard in the breeding of draught stock, the adoption of tractors in many cases being the cause of this neglect. The tractor, which had the effect of discouraging breeders of draught horses, is not likely to prove such a deterrent in future as it has in the past, unless, perhaps, if gas producers prove a success, and even if they do, we have still to meet the necessary costly repairs, which have to be imported. Many tractor owners are desirous of either reverting to or making greater use of horse power, and in many cases are prevented by doing so by their inability to purchase horses. The tractor slump is largely responsible for the high prices being realised for horses to-day, therefore some tractor owners are forced to continue with their tractors for the present, and if farmers do not breed draught stock there will be an acute shortage in the future, for not only a large number of the present tractor owners will require horses, but farmers who have relied solely on horses have many old ones which will need replacing. Horses are the best form of pulling power and are also best for both the health of the driver and the life of the implement. It is not a wise plan for farmers to breed the big, heavy horse for this district; the medium, nuggety draught is preferable. This type of horse stands up to the work and conditions better, does more work in less time than the heavy horse, and requires less feed and water. As his livelihood largely depends upon his horses, it behoves the farmer to give them reasonable care and attention. A good stable, warm in winter and cool in summer, will go a long way towards keeping horses fit and in good working condition. After long spells, horses should be stable fed for a few days before beginning to work; give them only a small amount of feed for a start and gradually get them used to feed. It is advisable to work for two or three hours only for the first day, gradually increasing the length of time until at the end of the week the team should work full days without showing signs of distress. If horses are worked full days from the outset, they rapidly fall away in condition, besides getting badly scalded shoulders. Working horses are only capable of doing a given amount of work each day; if pushed beyond this point, a reaction sets in and horses rapidly fall away in condition, and one will not accomplish any more work, in fact one will not accomplish as much, because the team will be worn out and will not travel nearly so well. To get the maximum work from horses they should be carefully stabled, have as much water as they will drink at least three times a day, and good, nourishing food, for preference, oaten hay chaff. Regular punctual feeding is of paramount importance. Always feed enough but not too much; be sure that they always eat all the food which is given to them. Horses should have free access to water; oftentimes when they first come in from work they do not drink properly. It should be the aim of every farmer to keep his horses in good condition. It takes less feed to keep them in good condition than it does to keep them in a poor condition. Do not work horses after sundown, the sweat will not dry overnight and is therefore likely to cause a chill and other illness. To work horses half an hour after sundown is much more detrimental to their health than several hours earlier in the morning. When driving horses do not 'push' them; they will go their own pace and will do much more work than the pushed horse in the long run. Horses should be well groomed each morning before they are put to work; this not only adds to their appearance, but also assists in keeping them in good health. It is not a wise practice to turn horses out on greenfeed on week ends in seeding time, as this is likely to cause scours. Use one more horse in the team than is

necessary to do the job; this not only considerably lightens the work, but the horses work along more quickly. Horses should on no account be tied up overnight; if they are managed correctly, they will feed all together at a long manger quite contentedly. The teams should be driven home from work and not let run on their own accord, especially when there are brood mares among them. The teeth of horses should have periodical attention; a large number of internal troubles are caused through defective teeth; amateurs should not attempt the cutting and filing of the teeth. The hoofs should also be cut and trimmed whenever necessary: if they are left unattended for any length of time they split and cause lameness. The manes and tails should have frequent attention. In connection with sore shoulders, prevention is always better than a cure; slight sores at times may be difficult and perhaps impossible to avoid, but if a team of horses is well cared for, one will seldom find sore shoulders. If, however, horses have sore shoulders, the best method to effect a cure is to put thin pads on either side of where the sore comes on the collar and also keep some softening ointment, such as medicated oil, on the sore. This will be a more permanent cure than if the horse was spelled until the sore healed. Do not spell horses which have sore shoulders, because experience shows that in the majority of cases the sore will again break open when the horse is put to work. Collars should fit well and be kept well lined; sweat marks and dirt should be cleaned off the collars and the horses' shoulders each morning before commencing work. The chains should be equal in length and free from wire or split links. Mares in foal should be worked on the outside of the team, where they are not so likely to get bumped, and thus cause the loss of either the mare or foal. Mares in foal should not be turned out in paddocks to spell; they are likely to get over fat, and when in this condition there is a danger of serious trouble at foaling. Mares that are used for breeding purposes should be kept out of any heavy pulling; ordinary work will not hurt them, in fact they should have light work right within a few days of foaling. When mares are about to foal they should be put in a separate paddock away from the other horses, and preferably near the house, so that they can be watched and have attention if necessary. Until foals are strong enough to look after themselves, keep them with their mothers, away from the other horses. When weaning foals put them in a paddock, where they can get plenty of exercise, water, and feed, and out of sight of mothers and other horses. If foals are properly handled from birth, they require very little breaking in, and if this method is adopted it will greatly minimise the risk of injury to both man and foal. When the foal is only a few days old it should be caught and handled and stroked and have its legs lifted. A small halter should be put on the foal and tied up for a few minutes. This handling should be repeated every few days until the foal is thoroughly used to it, when it should be taught to lead. Foals should not be tied up with a rope around their necks; use a halter and a rope and this will prevent choking down. If it is well grown, a colt can commence light work at 2½ years, but only worked for about two hours a day for the first few days, gradually increasing the length of time until quite fit to work with the rest of the team. Commence working a young horse in fallowing time, at that period a few hours lost is not so important as harvest or seeding. 'Treat horses well and they will give you good service'." (Secretary, B. Linke.)

KYANCUTTA.

November 7th.—Attendance, 13.

HARVESTER versus STRIPPER.—Mr. A. Simmons read the following paper:—"So far as costs are concerned the stripper and power winnower is a more costly unit—to the extent of approximately £100—than the harvester. At this amount, in due course, will be considerably reduced when after a season or two the harvester requires expensive new parts. I realise the extra labor attached to the working of a stripper to that of the harvester, but one is somewhat compensated for this by the maintaining a supply of feed, be it for working stock or sheep, and as too often has been the case, a shed or heap of cocky chaff has never been found to be amiss. It is here that the stripper has proved to be an invaluable machine. It has been argued that the harvester can do likewise in the saving of cocky chaff, but while this is granted to a certain extent, it has its disadvantages in the form of its carrying capacity, unloading, and the broadcasting of undesirable weeds. It oftentimes happens that certain sections of a crop are of a very light nature—necessitating the use of the stripper—and it is here that pride of place must be given this machine. In times of depression,

consequent upon low prices, the order of the day must be economy, therefore one cannot afford to purchase two machines when one can meet all seasons, good or bad, and still maintain the feed supply. The power winnower is also a labor-saver for saving and removing the chaff, for if a suitable frame is arranged on the wagon or truck it can be placed under the chaff elevator, and thereby loaded at will and removed to its destination. The running costs of the stripper are very light, and are few compared with that of the harvester; particularly would this be most noticeable when a stripper and harvester purchased at the same time had been running for a year or two. In many cases on the West Coast farmers are not blessed with an over-supply of horses, consequently they are working with the bare team of eight horses, and it is here again seen that all horses being workable, a change of team can be worked with the stripper, thus preventing the animals from becoming over-tired and saving any waste of time. The sample that each machine turns out: It is often seen that the harvester allows a certain percentage of chaff to congregate in the seedbox, this being due to the team slackening its rate of speed or taking the turns, which sometimes cannot be taken at other than snail's pace; but with the stripper the pace is not altogether an essential factor, for where the stripper has not really done its work, the power winnower will complete the job to the entire satisfaction of all concerned. I would not advocate the hand winnower to work in connection with the stripper, its progress being too slow with that of power. Should the elements prove contrary to seasonal expectations, a start can be made to clean up a heap or two according to size, and anything up to 200 bags or over can easily be put through, providing enough grain prevails throughout the heaps. Why I so much favor the stripper to that of the harvester is because the country generally is too rough for a heavy drawn implement; it is subject to severe straining, to say nothing of broken parts and hold-ups, and costly spare parts." (Secretary, E. Kelly.)

LAURA BAY.

December 12th.—Attendance, 12.

SEED WHEAT.—Paper read by Mr. E. Barnett:—"Care should be taken to select only seed that is true to type, free from disease, and free from barley, oats, &c. In this district most farmers rely on exchange of seed with their neighbors. Harvesting time affords the best opportunity to select seed in this way because it can then be seen which varieties have stood the test of the season. It is a good plan to leave a wheat crop that is intended for seed until the end of harvesting, because it stands a better chance of becoming bleached with rain and dews and is less liable to infection by smut. Farmers should change their seed wheat frequently to keep it true to type. To harvest seed wheat, only the stripper should be used. Choose cool weather and do not set the beaters too close to threshing plates; this method tends to avoid cracking the grain and injuring the germ of the seed. All seed should be graded. Where a grader is not available, it is a good plan to put the seed twice through the hand winnower, using the small zinc sieve. By keeping the sieve level and fairly full of grain most of the inferior grain and foreign matter can be floated off."

CARE OF FARM IMPLEMENTS.—Paper read by Mr. W. Bailey:—"The cost of implements and spare parts has so increased this last few years that it is necessary for the farmers to take every care of the machines, not only when working, but also during the times they are not in use. The plough or cultivator should have all bolts firmly screwed up, and the wheels washered and greased regularly. If an axle becomes so worn as to allow the grease to run out, it should be replaced with a new axle; this should apply to all machines, especially those having complicated parts. It is essential that every working part should have proper lubrication. Carry a small piece of wire with a tapered point for cleaning out all oil holes. Go over the implements at the completion of the season's work and see that they are in good order when needed for the next job. If this is done there will not be a last minute rush to get the machine ready to start work. The machine should not be worked with badly worn parts; this places a strain on other parts and makes it heavier to work and probably shortens the life of the machine. Cover up the drill and combine when left in the paddock, otherwise in case of rain the super gets wet, clogs the distributor cups, and perhaps breaks a casting. All super and wheat should be cleaned out when seeding is finished, the stars cleaned of all super, and placed in proper working order for the next season. On account of the many intricate parts of the binder, the farmer should take every care of this machine; all bearings should be kept tight in the sockets, and a little grease applied to the knotted and knife will prevent them from rusting when not in use. The canvasses should be slackened over night, and when not in use rolled up and hung in a dry place. A dressing of castor oil applied to

all belts will increase their driving power, preserve the leather, and grip the pullies much better. Keep the sprockets and pullies of the harvester and header in proper alignment. A good plan is to pour a drop of kerosene into all the bearings before putting in the oil; this will clear out any dust that might have collected and allow the oil to penetrate into the bearing. All harvesting machines, when placed in the shed, should have a block placed under the offside of the comb to prevent it from sagging and the belts taken off, oiled, and put away out of the heat. For the safe keeping of implements it is necessary to have a good shed to place them in out of the sun and rain, and this should be one of the main buildings on a farm." (Secretary, W. Edson.)

LONE GUM AND MONASH.

January 18th.

FRUIT DRYING.—The following points are taken from an address delivered by Mr. A. Ingerson:—The speaker contended that it was quite a proposition to pick to the color of fruit; to keep the various types separate in the buckets, even if it meant leaving some of the fruit for a second picking. "Work to sections of the block if the soils vary the type of grape to any extent," he said. "It may be well at times to keep the water off a particular patch in order not to delay a commencement of picking." The time to pick depended on the sugar content of the grape, but it was not possible to set a hard and fast rule, as what would be possible on one property might not be obtainable on another. He had no difficulty in obtaining 12 Baume, and that was a good test at which to start. For drying, the man with racks on his high land undoubtedly had an advantage; for the absence of moisture assisted considerably in hastening the drying. Keeping down the dust in the vicinity of racks, however, was an important factor. Around his racks a short grass grew quite freely, and this trampled down well and had the desired effect of stopping the dust trouble. Racks should run north and south, and be covered, and side curtains provided. "The use of side curtains," said the speaker, "could be overdone. They should not be used until the temperature was between 95 and 100 degrees or over." **Dipping Trouble.**—In dipping, the formula recommended was 1½ lbs. caustic soda, 2½ lbs. potash, and 1½ pints of pure olive oil to every 50 galls. of water. This was, of course, a formula to commence with, but the individual grower would have to vary the caustic according to the fruit he was treating. Should the 1½ lbs. not crack the fruit sufficiently, then add ½ lb. extra at a time until the correct strength is found. In mixing either the dip or the "stock pot" it was not necessary to have a boiling solution in which to dissolve the caustic, &c. It was all soluble in water, so mixing cold would be quite satisfactory. **Advantages of Mixed Dip.**—According to Mr. Ingerson, the main reasons why the C.S. & I.R. advocated the mixed dip were that in obtaining the desired results the cost in comparison with the cold dip was cheaper, and in the time of drying it had an advantage of from two to four days. In taking the temperature of the dip it was necessary to keep the thermometer away from the side of the dip so that a true reading might be obtained. The dip should not be allowed to boil. He changed the dip after dipping approximately 500 picking tins of fruit. **Temperature an Important Point.**—The temperature at which dipping took place was one of the most important points to watch. One must adhere to temperature, as it was definitely found out that

180 degrees F. was the lowest and best temperature of the solution. Up to 185 degrees was all right as a range of temperature, but not higher except under special conditions. Mr. Ingerson considered and had proved that at a temperature of 180 the fruit dipped dried normally the same rate as that dipped at 190 degrees, and the lower temperature gave the lighter color. It was advisable to remove the fruit to the racks as soon as possible after dipping, and the use of a tray on the rack was an advantage and a help in spreading. Fruit on the rack should be spread reasonably thin. *Spraying Not Advocated*.—Spraying the fruit was not advocated. It did not help to dry the fruit, and in hot weather sent it a brown color. Should bad weather be anticipated and it be thought the fruit had been underdipped, then the cold dip spray, if used, would act as a preservative. It was not advisable to take the fruit off the rack too soon, and yet not leave it on too long. It should come off at the earliest possible moment when it was tough enough not to break and yet pliable, as it was then in the best condition to take in the best values from the sunshine. "Dry thoroughly and depend on the packing sheds to add sufficient moisture by their methods of packing," was the advice of the speaker in this regard. Questioned as to the possibility of the Australian-made caustic soda being under strength, Mr. Ingerson explained that he had heard complaints, but he knew of some which had been tested and was found to be true to label, 98-99 per cent. pure. In dipping Lexias and Malagas the speaker stated that as the Australian Lexia required was of a light-brown type, he would suggest to dip at a temperature of from 185 to 190 degrees, and a caustic strength of about 1 in 18 or 1 in 20 (1lb. caustic to 20galls. water)—sufficient strength to just crack the fruit slightly. Oil should be added much the same as in the mixed Sultana dip, but the potash should be omitted. It was a mistake to crack the Gordo too much, which led to excessive sugaring of the fruit during and after packing. (Secretary, L. Bigg.)

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

January 20th.—Attendance, 16.

The first meeting of the year was devoted to weighing samples of wheat of the past harvest. Twenty-seven samples were submitted, ranging from 28½lbs. to 66½lbs. to the bushel—the average being 63lbs. (Secretary, C. Altmann.)

RAMCOO.

October 26th.—Attendance, 8.

THE USE OF SULPHUR IN ORCHARD OPERATIONS.—Paper read by Mr. J. Odgers (Hon. Secretary):—"Flowers of sulphur is the orchardist's standby in retaining color of tree fruits when being dried. In use it is necessary to keep the sulphur dioxide content of the fruit within the regulation limit of 14 grains. The only fruit that appears to cause any trouble in this respect is the apricot; the peach and pear it seems difficult to give too much with ordinary sulphuring. With the pear I generally give a double sulphuring—the whole of the fruit needs to be soft; a hard spot on the bottom of the fruit usually goes off in drying. An experiment in sulphuring apricots conducted a season or two ago for the Department of Agriculture gave as the highest sulphur dioxide content 10 grains, and the sulphur used was 2lbs. to the ½ ton of fresh fruit, exposed for five hours. Dusting sulphur on the vines is recognised as the correct method to adopt to hold oidium in check. Again, sulphur can be used to overcome black scale on citrus. Choose a calm night and place a tin or two containing sulphur under the orange tree affected with scale; set alight to the sulphur and allow the fumes to rise into the tree, and it will kill the scale. These, of course, are well known and understood uses of sulphur in the orchard, but its use in the soil seems to be a question only lately come into use, and the average grower has but a hazy notion of its use, what it is put there for, and if it really does do any good. It is debated by some growers that if sulphur is ploughed in under the rows of vines the fumes rising during the hot weather tend to check an attack of oidium. Probably there is something to be said for this practice, but whether the quantity of sulphur so used is a payable

proposition, compared with the dusting of the vines, is open to criticism. Others argue that the sulphur ploughed in is a manure and increases the crop, but they cannot tell what constituent in the soil it provides or whether their crops have improved by its use. Mr. G. Quinn (Chief Horticultural Instructor), in speaking of sulphur, said it was not a direct manure, but that field dressings had given a definite increase in yield, especially in growing leguminous crops. Professor Prescott advises, for the improvement of the river soils, applications at the rate of 5cwts. to the acre. Ordinary commercial sulphur can be used, but it must be very fine. At the last River Conference Professor Prescott said that in California they had discovered a bacteria that caused the oxidisation of sulphur. This bacteria was not known in Australia, and at the Waite Institute they set to work to try and find it. After two years' work they had succeeded in isolating a bacteria that caused the oxidisation of sulphur. It had been proved that the treatment of our soils with sulphur gave very promising results, and seemed to supply the soil with a very useful tonic. From the above it would seem that an experiment with sulphur tried on a few trees, or a row of vines, would be educational, if not profitable. A short time ago I saw a report of an experiment with sulphur that was very interesting. A grower had a garden containing a few apricot and peach trees which suffered badly from shot hole and curl leaf. One winter in an apricot tree about 15in. to 18in. from the ground a hole 1½in. in diameter was bored with an auger diagonally towards the heart of the trunk. The hole was then half filled with flowers of sulphur and plugged. The tree that year produced a heavy crop of fine fruit with not a sign of shot hole, and right through the season the tree was a picture of health and vigor. A peach tree treated the same way acted in a similar fashion, and was free from curl leaf. Commenting on this experiment, Mr. E. C. Grasby wrote: "I was much interested in the experiment with sulphur, as I had been

treating my trees for the past eight years in a somewhat similar way, and during the whole of that period I did not have to spray for any disease, the trees being very clean and the crop of fruit heavy. The trees treated included fully grown apricots, nectarines, and Elberta peaches. The method adopted was that about 4lbs. or 5lbs. of sulphur were scattered around the base of each tree during autumn and lightly forked into the ground. The trees responded well to the treatment and grew very strongly, and all carried heavy crops each year, the fruit being of good size and clean. The idea came from a pamphlet speaking of the excellent results obtained in California by treating the prune with sulphur, and the writer decided to experiment on stone fruits with the foregoing results." If Mr. Grasby's operations can be applied to all soils with similar results, then shot hole and curl leaf can be controlled by treatment much less drastic than that of the previous experiment, and the crop yield increased and improved in quality. The results claimed are so good that it would be profitable for growers to definitely experiment on these lines." A good discussion followed, though members had had little actual experience. Mr. J. Boehm had tried sulphur on 50 orange trees, using 3cwts. and 5cwts. He had no sooty mould, but trees alongside looked better. Mr. I. Darling had dusted and ploughed in sulphur, and still had oidium. Mr. F. Lewis considered air and light better than sulphur. Mr. A. E. Seary said dusting vines with a mixture of sulphur and air slaked lime had a favorable effect on vines with black spot.

SOUTH AND HILLS DISTRICT.

CURRENCY CREEK.

December 4th.—Attendance, 10.

EXPORT OF EGGS.—Paper contributed by Mr. W. Robinson:—"In the early days of export no eggs were sent away from Australia after the middle of October, but now owing to the great increase in production it is essential to export eggs during December, and last year exporting was continued up to the middle of January. The cost of placing the eggs on the London market is 7d. per dozen. This covers the cost of cases, fillers, freight, commissions, wharfages, &c., and it is a good thing that the exchange is in favor of the producers to-day, as otherwise the net return to the poultry farmers would be very low. If eggs are selling at, say, 10s. per long hundred in England, the exchange, which is equal to 2s. 6d., makes a total of 12s. 6d. This is equivalent to 1s. 3d. dozen; from this is deducted 7d. a dozen for expenses, which leaves a net return of 8d. to the producer. London buyers to-day, however, are only offering 9s. 6d. per long hundred for eggs for shipment during December, and therefore the best price that can be offered to-day for export quality eggs is 7½d. dozen. Farmers would be well advised to take every care of their eggs, because for pulping purposes the eggs are only worth about 4d. to 5d. dozen. *Egg pulp* is manufactured by hand-cracking the eggs, which have been previously tested as to quality. The liquid is passed through various processes to break up the yolk. The pulp is cooled and tinned in various size tins, the most popular size on the London market being the 40lb. tin. The pulp after being tinned is put into a freezing room, the temperature of which is down to zero, the egg pulp is frozen hard, and it is kept at this temperature until it reaches the baker, either in Australia or in London. If the pulp goes to London it is kept down to a very low temperature on the boat; the freezing-rooms do not go above about 5 or 10 degrees. There is no preservative used in egg pulp, and all the baker needs to do is to allow the pulp to thaw before using it. When the eggs arrive at the exporting floor they are unpacked, and each egg is individually tested. The air cell of the egg should not be larger than a 6d. piece and should be quite firm. Eggs that have shaky air cells cannot be exported to London, and have to be used

for either local trade or for pulping purposes. Eggs for export are packed in 30 doz. cases and fillers. The eggs are graded and exported in 13½lbs., 15lbs., and 17lbs. packs. This means that 10 dozen eggs weigh 13½lbs., 15lbs., or 17lbs. respectively. The 13½lbs. eggs are 1½ozs. in weight, 15lbs. pack eggs weigh 1½ozs. and up to 2½ozs., and the 17lbs. pack weigh from 2½ozs. up to 2½ozs. Eggs are sold in London by *long hundred*, a trade term which means 10 dozen., so that each case holds three long hundreds. After the eggs have been packed they are placed in a cool room, the temperature of which is about 33 degrees; the eggs are sent down to the steamer in cool cars, unloaded on the ship's side and placed into the cool storage chambers on the boat, the temperature of which is kept at about 33 degrees all the way to London. The export of eggs has increased considerably from Australia during the last five or six years. The poultry industry has proved to be of great value to the Commonwealth, and is responsible for the employment of hundreds of thousands of people. The cases create work for timber men; the cardboard fillers for filler manufacturers, and carpenters have to be employed for assembling the cases. Then again the wharfmen and railway men are provided with work, and millions of bushels of wheat, bran, and pollard are consumed every year by fowls. The best time for exporting eggs to London is during August, September, and October. The prices on offer during these months are fairly good, but after the end of October the London buyers pay less for the eggs, as they arrive on the market at a time when prices are generally lower. First, it is essential that the producer should take every care and collect eggs from the nests as often as possible—no less than at least twice a day. The nests should be clean, and any eggs that are stained cleaned immediately after they are picked up. The cleaning should be done with a damp rag, and the eggs must not be washed on any account, as this has a detrimental effect on the keeping quality of the eggs. Carbonate of soda is a good thing to clean eggs, and the damp rag should be dipped in the carbonate of soda powder and rubbed on to the egg; this will be found very effective. To get the best results eggs should be marketed at least twice a week, forwarded to the exporting floor in cases and fillers, and not packed in chaff, as the eggs keep much cleaner in the fillers and carry better on the railways or by carrier. The Chinese are our biggest competitors on the English market; they are able to produce eggs cheaper and their labor costs are much lower. We are further away from the London market, and it costs us more to market our pulp. The price for pulp is certainly low and unpayable to the poultry farmer, and it is all the more necessary to look after the eggs so that the bulk of them can be sent away to London as eggs in shell; thereby the poultry farmer is able to get better returns." (Secretary, D. Jeff Gordon.)

FENCING.—The following paper was read by Mr. Nielsen:—"Points to consider in the erection of a fence are neatness, adaptability to stock resistance, and economy of time and labor. It is necessary to have suitable tools for erecting the fence and splitting the posts. Tools required for the latter are a sharp axe, well ground back on the steel; a crosscut saw; and a set of wedges, 12in. x 2½in., 9in. x 2½in., and 6in. x 2½in. **Selection of Timber.**—First note the height and thickness of the tree and examine the bark, which is a sure indicator of how it will split. If straight in the fibre and running straight up the trunk without any twists around the trunk it will be a good 'splitter.' Look for any old dry branches of any consequence; if the main branch of the trunk is in the above condition it will surely be decayed in the heart. Next look for the number of branches; if numerous and close together on the trunk, the tree will be awkward to split, for even though the branches are lopped off close to the trunk, the split has a tendency to follow the curl where the branch has been. After having selected a tree, fall it in the most convenient place to work. Next mark the length required for the posts; 5ft. 6in. is the usual length. It is necessary to remove the bark where the timber is to be sawn, otherwise the saw will jamb and possibly take the set out of it. The wood is now ready for the wedges. Take the two smallest wedges and enter one half-way between the centre and the bottom, the other between the centre and the top. Drive these right in, then a crack should appear along the top, put the next to smallest wedge in this, and enlarge until the log falls apart; doubling the big ones will hasten this if done carefully. Then split it into the required size posts. **Erecting the Fence.**—First find the survey pegs and drive erect over them firm straight pegs, about 4ft. 6in. high. This will provide a sight line. Then decide which end to start and place a strainer there, which should be not less than 3ft. 6in. in the ground, 2ins. higher than the smaller posts, to allow for straining the barb. The distance apart of posts and height above ground is a matter of opinion. If they are as far apart as three to the chain, a dropper in

between will strengthen the fence. I favor the fence with the greater number of posts, because they are best to resist great cattle, for which most fences in this district are required." (Secretary, A. Eve.)

INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

February 15th.—Attendance, 11.

LESSONS FROM 1933.—In the course of a paper on this subject Mr. W. Beresford showed how commodities, such as butter and wool, were governed by supply and demand, consequently prices had been very low for butter, and enhanced values for wool, brought about no doubt by the shorter supply. He had found a comeback sheep the most profitable—for a twofold purpose; wool and the mother of a lamb. He advocated the months of November and December as the best time to dispose of surplus sheep. He emphasised the folly of overstocking, and pointed out by figures that a flock of sheep kept in good condition was far more profitable than twice the number neglected. Foot rot was becoming more prevalent, and needed careful attention. It could be combated successfully if sheep were treated with a foot bath every three or four weeks. Serious cases could be dealt with more often by way of leather boots containing a disinfectant, such as bluestone, or tar. The boots could then be tied around their legs and left for some time. This he had proved to be very effective for serious cases. Meadow hay should be cut and stored for a lean period. Too much reliance should not be placed on spring rains. Conservation could be assisted by closing up the paddocks earlier. He advocated *Phalaris tuberosa*, as a grass that was liked by all stock, and more so because it was a perennial. To get a good germination it must be planted on a prepared seed bed. (Secretary, W. K. Mayfield.)

MILANG (Average annual rainfall, 14.97in.).

December 2nd.

MANAGEMENT OF THE LUCERNE PLOT.—Paper read by Mr. A. Matheson:—"There are very few places in this district where lucerne can be said to flourish without irrigation. This district has an abundance of sub-artesian water, and if utilised wisely, with the help of cheap power, will encourage intense culture and closer settlement. That lucerne can be grown anywhere in the district is quite evident, although there are natural conditions where it is much easier established. For irrigation purposes, land that has good drainage is much to be preferred, more particularly in this district, where the water for pumping purposes has a percentage of salt in it. In choosing a site for an irrigated lucerne plot select a sloping sandy rise with a grade of say 6ins. or less to the chain. Lucerne can be more easily established on the stiffer soils, because while the seed germinates readily in sand, there is a likelihood of the young plant being burnt by the heat of the sand, unless the ground is well covered. The sand, being of a loose nature, does not retain its moisture if not covered for any length of time. This can be overcome with sprinklers, but in flooding the young plants, great care must be exercised, since there is always a tendency to wash out. There is not much fear of not establishing a good plant where weather conditions are suitable, but if this fails, great difficulty may be experienced in re-seeding, because the young plants are deprived of the moisture by the stronger plants, although this can also be avoided where sprinklers are used. The sandy rises are preferred, because with proper treatment better results will be obtained and more use can be made of the heavier land. One of the drawbacks of putting lucerne on sandy rises is the fear of the 'blow,' which will soon injure the young plants. To avoid this sow a covering crop, but where there is danger of the soil blowing, it is advisable to cover the plot with well-rotted manure. This takes time, of course, but it repays for the labor, for besides stopping the 'blow,' it adds humus to the soil. A proper soil preparation is essential, although in favorable years it may be possible to get a good plant with indifferent cultivation. The usual way recommended for sowing lucerne is to roll the ground, broadcast the lucerne, say, 16-20lbs. per acre, then lightly harrow, preferably by dragging a hoe over the sown area. An excellent germination can usually be obtained by sowing early in July, through the drill, mixing the seed with super. It is advisable to sow immediately after mixing, because with most other small huskless seeds, there is always a likelihood of killing the germ of the seed. Six inches of water is necessary to get the best results, irrigating if possible every three weeks. Where the water was given to the above requirement I have cut after four to five weeks' growth a crop over 3ft. 6in. in height, and within 2 yards not half the growth, showing evidence of neglect. This result tends to show the need for harrowing the ground, or grading it to allow equal results when watering.

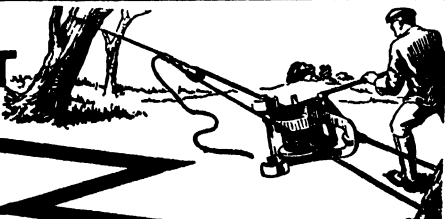

The main essentials for lucerne growing are plenty of water and warm weather. While this is one of the main needs in successful lucerne growing, another necessity is to thoroughly cultivate the lucerne plant at least once a year, some times during the winter months. An interesting illustration of what cultivation will do was shown on a portion of the plot which had such a thin stand that it was decided to take it all up and re-sow. An old spring time was used repeatedly and the lucerne was not killed out, but by October of the same year where this treatment was observed it showed fully 100 per cent. over that which was cultivated in what was considered the usual way. To get the best out of land it is necessary to put back into the soil what the crops have taken out. This necessitates putting heavy dressings of suitable manure on the plot—stable manure and 1cwt. to 2cwts. super per acre. Associate this with good cultivation and abundance of water and an abundance of green lucerne for the summer months should be the result. I regret I did not practice what came under my notice some time back. A farmer at Strathulbyn has demonstrated that lucerne can be grown very successfully under somewhat adverse conditions; he obtained a wonderful growth where previously poor crops were grown. His practice was to cultivate the lucerne right through the winter months, not allowing weeds to grow. Is the method I have adopted sufficiently payable to recommend others to practice it? Under present conditions of low prices and high costs of production I believe that if the capital is available, to invest in an irrigation plant; using a good crude oil engine it pays as well as anything else. Lucerne cheapens the feeding of fowls and pigs as well as cows. It is not a balanced ration by any means, but it is one of the main factors in a good ration." The discussion on the paper was excellent. Mr. B. Casley gave his views on lucerne growing on the Murray swamps and in Tasmania. Questions were answered and a large amount of information gained through the paper. (Secretary, L. Yelland.)

MASON-WORK WALLS.

[Paper read by Mr. W. Bourke at the January meeting of the Laura Bay Branch.]

In the building of such walls it is always advisable to go to a little extra trouble and time and put in good work rather than slum the job, for well-built mason-work will last very much longer, and therefore pay for the extra trouble and time. *Selecting the Material.*—I strongly advocate using newly burned lime. It is always better to use hydrated lime—quicklime slaked with just sufficient water to slake it. The reason for this is because quicklime that has just been bagged from the kiln and allowed to air slake without the aid of water does not bind well, and it is very apt—particularly in plaster—to cause some to powder and not set. All lime should be well sifted to remove charcoal. *Choosing of the Sand.*—Any good, clean, sharp sand can be used. Some masons like a good coarse shellgrit, others a good wash sand from the roads, and others prefer a good pit sand. I favor pit sand, particu-

TEARING THEM OUT

is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed. It develops the power of 250 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognized its merits and applied its help.

larly over-wash sand from the roads, because apart from this sand being apt to have a certain percentage of dirt with it, it is also likely to contain a proportion of magnesia, which is very detrimental. In many cases one has to take what is available, and provided there is no magnesia or dirt mixed with them, any of the above-mentioned sands are quite good. In choosing the stone be particular that it is not quarried from any soils that contain magnesia. Always try to get a stone that is easily trimmed, because in this lies the whole secret of quick building and good tying of the wall. *Mixing.*—For ordinary building work it is always advisable to mix all mortars at least two or three days ahead for building, and in the case of plastering the mortars should be mixed at the very least a week ahead, and if it can be managed it should be left longer. In leaving the mortar to stand mixed ahead of time, it will be found that it binds better, is better to work with the trowel, and gives any little lumps of lime a chance to slake out and be mixed into the mortar when it is remixed for use. There are two ways of mixing the mortar. One is to mix the required quantity of sand and well-sifted lime together thoroughly in the dry state, then add sufficient water to make the mortar again working thoroughly. The next way is to mix the lime and water together in a suitable vessel and then pour this mixture on to the sand. This method—providing one is used to it and knows how thick the lime-water needs to be to get the mortar of suitable thickness—is better, because besides being sure of the lime being well slaked, all charcoal can be removed from the lime; it will float on the lime-water. For the amateur, I advise the first method. The usual quantities are: 1 kerosene bucket of lime to 3 buckets of sand for ordinary building, and 1 kerosene bucket of lime to 2 buckets of sand for plastering and flushing up. In commencing the building, pay great attention to the foundation. A good foundation is very essential. Where stone is not very deep a trench about 4ins. wider than the wall is intended to be right down to the stone will suffice and commence the foundation from this point. Where stone is not shallow, the trench should be sunk down to a depth ranging from 18ins. to 3ft. according to circumstances, such as the nature of the soil and the weight of the building to be placed on the foundation.

When starting the walls, the first thing to do is to set up the line to build between. To do this, first build up each corner to the height of about 2ft. or 3ft.; in doing this be very particular that the stones are well tied both on the outside and inside, and where possible put in a “througher,” i.e., a stone that goes right through from the inside of the corner to the outside. Also when putting up these corners use the spirit level when placing every corner stone. At this point, do not leave anything to chance. It is very essential for the corners to be perfectly level and upright, because it is from these points that the lines from the rest of the building are taken, therefore do not spare the spirit level. When the lines are set up from these points, take notice of the winds if they tend to blow the lines at all, build up a piece or two, according to the length of the wall, in between the corners to stop the lines blowing about. Also when building up these pieces, use the spirit level freely. At all times when building tie the stones well, and as often as possible, and also put as many “throughers” in the wall as possible, because these tend to make the building much stronger. When filling in between the inside and outside stones do not fill up with small stones and then place the mortar on top, because if the mortar is not very thin it will not run through the stones, and therefore leaves hollows in the wall. Always put the mortar on first and then push the small stones into it and then put more mortar on top.

WOMEN'S BRANCHES.

THE FOOD VALUE OF MILK.

THE NUTRITIVE VALUE OF PROTEINS.

[Continued from page 911.]

Previous to 1912 a discussion of the nutritive value of any foodstuff would have been confined to a consideration of the total quantities of protein, fat, carbohydrate, and salts it contained and of its value as a source of energy, that is, its calorific or fuel value.

As a result of work that has been done at this station and later in other laboratories, the field for discussion has become much broader, for it was demonstrated that the *quality* of the protein present in any food is of even more importance than the *quantity*, and a realisation of the essential role that the vitamins play in normal nutrition has raised many more problems.

FIGURE 1.

Milk contains several different proteins, but there are only two that occur in notable quantity: *casein*, the protein found in cheese, and *lactalbumin*, the principal protein of whey. These two proteins differ not only in their chemical structure, but also in their nutritive value. Both suffice to promote the normal growth of young rats, but lactalbumin is somewhat more efficient for growth than is casein, for in comparable periods of time a given quantity of lactalbumin will enable an animal to gain about 33 per cent. more in weight than will the same amount of casein.

This is instructive from a practical standpoint, for it demonstrates that the whey—a by-product of the manufacture of cheese—contains one of the most valuable food proteins known and should not be wasted. Casein, which forms about 80 per cent. of the milk proteins, is easily digested. This property makes it especially desirable as a food for infants or persons with weak digestions.

For centuries people have been accustomed to use foods of animal origin together with bread and the other cereal products that form so large a proportion of the average dietary. Bread and milk, eggs on toast, meat sandwiches, and the use of milk on breakfast cereals are a few illustrations of this custom. If any one who was enjoying a meal of any of these mixtures, were asked why he choose the combination of the animal with the vegetable product instead of eating either one alone, he would probably say that "it tasted good," or "it satisfied his appetite better that way," or something else equally indefinite.

If an animal is fed on wheat flour as the whole source of protein in an otherwise adequate ration, it will grow very slowly, if at all, even when relatively large amounts of the proteins are eaten. If, however, one-third of the wheat protein is replaced by an equivalent quantity of protein in the form of milk, eggs, or meat, the animal will grow at a practically normal rate.

FIGURE 2.

Rat 5277 was fed on a diet in which gliadin from wheat flour furnished the protein. On this food he gained only 10 grams in 10 weeks. Rat 5314 was fed on a mixture of wheat flour and milk. On this food he gained 180 grams in 9 weeks. This illustrates the importance of combining milk with the cereals instead of feeding the cereals alone.

To illustrate this, as well as the results of other experiments with various diets of known composition, charts are employed which give the curves of body weight during the time of feeding. In these charts the squares running horizontally represent the duration time of the feeding experiment expressed in days; those running vertically express the weight of the animal in grams (1 gram equals about one-thirteenth of an ounce). The heavy black lines show the rate at which the animal gained weight; the more nearly vertical these lines the more rapid the growth.

Figure 1 gives a graphic representation of the growth rates of a number of rats which have been fed in these ways, and in Figure 2 are photographs of two of these animals.

All of the animals shown on this chart were of the same size and age at the start, and were growing vigorously when put on the experimental diets. The differences in size at the end of each experiment were due solely to the protein of the diet. In this series of experiments the percentage of protein and the nutritive ratio* of the mixtures were practically identical, the foods differing only in the kind of the protein. The animals in the group labelled "flour" received all of their protein from wheat flour, those in the groups labelled "flour + milk," "flour + egg," and "flour + meat" received a diet in which the total concentration of

FIGURE 3.

The contrast between feeding a good or bad protein to a young rat. The upper two rats are 5 months old and have been fed on diets exactly alike except that the one at the top had casein from milk on which it grew normally and the one in the middle had gliadin from wheat flour on which it could not grow at all, so that when it was 5 months old it weighed exactly the same as the rat at the bottom which was only 1 month old.

protein was the same as in that of the "flour" group, but one-third of the protein was furnished by milk, eggs, or meat, respectively, the remaining two-thirds being furnished by flour. It is obvious that relatively small quantities of these animal proteins greatly improve the value of the food for growth. The value of these animal products lies in the fact that they are so constituted as to supplement the chemical deficiencies of the flour proteins.

The proteins are broken up by digestion into amino-acids, which are then used in constructing the new proteins of the tissues of the growing animal. Unless the food protein furnishes a sufficient amount of certain of these amino-acids, which

* The nutritive ratio of a diet is the ratio of the calorie value of the digestible protein to the combined calorie value of the fats and carbohydrates therein.

are needed to make the tissues required for normal growth, the animal grows correspondingly more slowly than it would if more of the needed amino-acid were available.

Wheat flour contains two proteins one of which, gliadin, yields only a very small amount of the amino-acid called lysine. The effect of a limited supply of lysine on growth is illustrated by rats 5277 and 5265, whose curves of body weight are shown in Figure 1. These were fed on a diet in which all of the protein was furnished by gliadin. They were maintained in good health, but gained only about 10 grams.

FIGURE 4.

The lower photograph is that of a rat which has been fed for 7 months on a diet containing zein (one of the proteins from corn) together with a small amount of amino-acid tryptophane. On this diet the rat could live but not grow, and the upper photograph is one of the same animal taken a few months later, after casein from milk had replaced the zein and tryptophane.

The rats on the "flour" diets grew somewhat more than those on the gliadin food because flour contains another protein which yields more lysine than does gliadin and hence supplements to some extent this deficiency of the gliadin. However, the amount of lysine thus supplied was too little to promote normal growth. In this connection it is interesting to note how perfectly a young animal can be maintained in health, but without growing, even for a very long time when its diet is adequate in respect to everything except the chemical constitution of its food protein.

Two foods which thus far have proved to be efficient supplements to flour are milk and eggs; either of these is somewhat better than meat. Thus, under similar conditions of feeding when the food contains two parts of flour proteins to one

part of meat protein, rats gain about three times as much per unit of protein eaten as when flour furnishes all the protein, and nearly four times as much when milk or eggs are used as supplements.

Figure 4 shows in a striking manner how essential it is to supply the young animal with protein that furnishes sufficient lysine. The lower picture is that of a young rat that lived for 7 months in perfect health on a food containing zein + tryptophane as its sole protein. During all of this time it failed to grow and weighed only 70 grams. It did not even show signs of maturing but looked exactly like a recently-weaned rat; it remained a baby. At the end of 7 months casein was used to replace the zein + tryptophane. No other change was made in the diet. During the next 3 months it grew at the normal rate to 240 grams and as the upper picture shows, became a fine, vigorous animal.

FIGURE 5.

What this means might be illustrated in this way: For about one-fifth of its life period the rat did not grow. Calling a man's span of life 70 years the case would be somewhat like that of a boy, kept as a healthy infant in arms until 14 years old—weighing perhaps 16 to 20 lbs.—and who, by a change of diet when 14 years old, attained a man's size and weight at the age of 21.

Two of the rats, 5293 and 5316, whose graphs of body weight are shown in Figure 5, received a ration in which the protein was furnished by gluten feed. Rats 5302, 5318, 5287, and 5315, on the other hand, had two-thirds of their protein in the form of gluten feed and the other third as milk or meat. The nutritive ratios of all of these three foods were alike, but the results were strikingly different.

This juggling with proteins and amino-acids is very interesting to the chemist and physiologist, for it represents a triumph of science that excites the wonder of those who appreciate the almost insurmountable difficulties encountered in these investigations. It would be of little use to discuss it here if these facts could not

be applied to the feeding problems of the household and farm. Amino-acids are not commercially obtainable but products are at hand which contain proteins that furnish these amino-acids in readily obtainable form.

When whole corn is fed, the other proteins in this seed supplement the zein to such an extent that the animal can grow slowly, but if the corn is combined with milk, the proteins of which are rich in tryptophane and lysine, growth is very rapid. Thus it appears that the chemical constitution of the protein of the food

FIGURE 6.

Photographs of some of the animals whose curves of body weight are shown in Fig. 5. Although all three were of the same age, rat 5302, which had received a mixture of gluten feed and milk, is nearly three times as large as 5293, which received the gluten feed alone, and is more than four times as large as 5292, which was fed on zein plus tryptophane.

influences growth and that it is absolutely necessary to provide animals with proteins of the right kind, if they are to grow well. This applies not only to growth, but also to milk or egg production. Both milk and eggs are rich in protein. The animals producing them need large amounts of protein in their food, but until the differences in chemical constitution of the proteins of different feeds were discovered, it was not appreciated how important it is to provide proteins of the right kind.

(To be continued.)

WHY NOT EGGS?

[By ABBY L. MARLATT.]

*(Special circular issued by the Extension Service of the Wisconsin, U.S.A.,
College of Agriculture.)*

The value of the egg was recognised in early history not only in the diet but also in the superstitious rites dealing with the mystery of the origin of life, and even in the foretelling of the future.

So great a respect was there for the germ which "nature had destined for the production of chicken" that among the early Greeks the abstinence from eggs was increasingly recommended. The egg was venerated as the symbol of the world and the four elements. The shell "represented the earth; the white, water; the yolk, fire; and the air was found under the shell."

The Romans, while they revered the egg, served it at the beginning of a repast. Horace speaks of remaining at the table from "the egg to the apple," since the apple came last in the feast. The Romans preferred the soft cooked egg and took it directly from the shell "in one gulp."

The use of the egg during celebrations of the seasons of the year, especially the New Year, is an old custom in both Asia and Europe, and even the use of different colors in dyeing eggs is recorded. The Christian Church adopted many of the older customs; hence we have the use of eggs on Easter Sunday as part of the festival.

Eggs have long been a favorite food and also are of real value in promoting health. Not only do eggs build muscle but they also supply some of the necessary vitamins and valuable minerals which the body needs. For the child, eggs are especially necessary.

Of course, it is important to buy clean, fresh eggs from a reliable dealer and to keep them in a cool, dry place—preferably in a covered dish in a refrigerator.

The muscle building value of the entire egg is high, due to its proteins. Therefore, it is not necessary to serve meat and eggs at the same meal. When eggs are used with cereals, peas, beans, and most of the other vegetables, as well as with gelatin, they enrich and make them adequate building foods. The rule to-day is to serve a muscle building food in at least one of the meals of the day. This is essential for the growing child; hence both milk and yolk of egg should be included in the diet of the child under five.

YOLK RICH IN VITAMINS AND MINERALS.

The yolk contains vitamins A, B, C, D, and G, as well as a large amount of phosphorous and iron in easily usable form and a small amount of copper—so needed in blood building—as well as other useful minerals.

The egg yolk is valuable in preventing rickets, which is a condition shown by enlarged, crooked or bent bones. The right balance of phosphorus and calcium along with vitamin D will prevent and even cure rickets, hence the need for the yolk of egg and milk in infant feeding.

Dr. Dorothy Reed Mendenhall, of this department, recently stated: "If every child, after it was one month of age, had the yolk of an egg every day it would probably never have anemia."

The fat in the yolk of egg is in a form which is easily digested. The yolk is also richer in solids than is the white since it contains only 50 per cent. water.

The presence of iron is shown in hard cooked eggs at the point where the white and yolk touch. The white of the egg when heated gives off a sulphur compound that reacts with iron, coating the yolk and staining the white. The egg is just as valuable in this form although somewhat unsightly. To avoid this discoloration, cook the egg in the shell at a lower temperature for a longer time.

For the adult the building protein may be taken from many different sources, but none is better than that from the egg itself. Of course, in health the adult needs only to repair the body, not to build new tissues. In diseases that tear down tissue the yolk of the egg is used in increasing amounts. Egg yolk, either raw or just coagulated or finely divided hard boiled, is easy to digest.

It is seldom advisable for children to eat egg white raw. For normal adults it is probably not objectionable, but to give the raw egg white to infants may produce a sensitization to the egg white that shows itself in digestive disturbance or even skin eruption. Hence, use only the egg yolk for infants.

EGGS EASILY DIGESTED.

Both yolk and white, when cooked at temperatures that leave them jellylike, are very easily digested. If hard cooked eggs are put through a sieve or chopped very fine, they are found to be easy to digest in this form also.

The white and yolk will cook far below the boiling point of water (134° F. to 180° F.). This is even below the simmering temperature of water, so that in cooking eggs in the shell or poaching eggs out of the shell, putting the cold egg into boiling water and then placing to one side to let the temperature fall slowly will give excellent results. In the laboratory it was found that the least amount of boiling water to use in cooking an egg by this method is 1½ cups of water to each egg. This rule should be followed both in poaching eggs or boiling eggs in the shell for best results.

STORAGE EGGS GOOD AS FRESH FOR COOKING.

For ordinary cooking, storage eggs are just as valuable as fresh eggs. Recent studies showed that a good angel food cake could be made from eggs that had been kept in storage from seven to nine months, although it was necessary to add water before beating the whites to make up for the loss from the weight of the egg. The cake was faintly yellow and not quite so light as that made from fresh eggs but would be called a fair angel food. In fact, the beating quality of the freshly laid egg improves slightly up to the second day and keeps this value for 28 days under good storage conditions.

Even when the white of the egg after long storage has lost water slightly, the addition of an equal amount of water will improve the beating quality. This seems to show the beating value of the egg depends on the nature of the egg white but varies with the loss of water.

The common test for freshness is based on the egg not having lost moisture, shown by the tiny air cell at the end of the egg. The fresh egg sinks in water. The egg that has lost part of its moisture and has had this replaced by air, increasing the air cell, will tend to rise in water. Candling eggs is an ancient Egyptian practice. To-day it is done by holding the egg and rotating it in bright light. If the air cell in the large end is small the egg is likely to be fresh.

HOW STORAGE AFFECTS EGGS.

At present, due to the improvement in cold storage, it is possible to keep eggs in good condition from eight to ten months. The best commercial method is to seal the shell and keep the egg cold.

The newest storage method is the vacuum treatment used in the United States Department of Agriculture. Air is removed from the storage area and carbon dioxide substituted. Eggs treated in this way lost one-tenth of 1 per cent. in weight in 10 months whereas storage eggs usually lost 18 times as much.

The amount of moisture lost in storage is an important thing to consider in buying eggs for it reduces the weight of the egg and may affect the color of the white. It increases the air pocket so that when heated it expands and breaks the shell with loss of white.

In the home economics laboratories at the University of Wisconsin it was found that there is probably no loss of vitamin D in eggs stored from six to seven months at 40°F. nor in fresh eggs which had been dipped in hot fat, 375°F. for five seconds or dipped in hot water, 205°F. for five seconds. This method of home storage of eggs is, therefore, possible. However, the best home storage method is sealing with water glass. The difficulty is that waterglass weakens the shells so that if the eggs are packed in too many layers some of them may break and spoil the solution in which they are packed.*

The size of hen's eggs varies according to the age and breeding of the fowl, the smallest being laid by the pullet. The weight of the egg may vary from 1oz. to 3ozs.

The food value, regardless of size, is quite dependent on the diet of the fowl itself. The color and vitamin content of the yolk are quite dependent on the hen's feed and on the amount of sunlight, artificial ultra-violet light, fish oils or other sources of vitamin D she received. To know the source of the egg, therefore, is as important as to know the age of the egg if we are going to get our money's worth.

USING YOLKS AND WHITES.

One of the economies in the use of egg white and yolk separately is that many dishes that are especially valuable for the child call for yolk of egg only. The white of the egg can be placed in a jar, sealed and put into the refrigerator and will keep perfectly for days. The yolk, on the contrary, has to be covered with a layer of water before sealing to keep the surface from drying.

The fat of the yolk if mixed with the white lessens the beating quality of the whites; therefore, in breaking eggs it is important to keep yolk and white separate. A fresh yolk does not break easily because it has a tough protective covering. As the eggs get older this protective covering seemingly becomes tender, and hence in eggs that have been kept for some time there is a greater danger of the yolk breaking and a part mixing with the white. Fortunately, in the art of cookery there are many recipes calling for the white and the yolk used together so that when this occurs, change the recipe "and go again."

USES FOR EGG WHITES.

Egg whites are used in all dishes where the beating of the white encloses air which makes the product light and fluffy. The week-old egg beats better than the newly laid egg, as it has had time to lose a little water. Experience has shown that adding a pinch of salt tends to increase the beating quality of the fresh egg. There are many uses for egg whites, including the following:—

Angel food cake, white cake, kisses, and tarts.

Soufflés, both fruit and vegetable.

Fruit snows and sherbets.

Frostings and fillings.

Meringues for pies and puddings.

Cookies.

Clarifying agents for soups and coffee.

*Earthenware crocks or wooden pails are the most satisfactory containers. Waterglass can be bought at any store, but purchase only enough to preserve the eggs which you expect to put down this year. The proper proportions for mixing are 1 part (about 1 pint) waterglass to 9 parts boiled water, which has been allowed to cool. Stir the mixture thoroughly, pour it into the crock or pail, and put in the eggs. Waterglass in powdered form is also on the market. This, if dissolved according to directions on the package, is more reliable than the liquid form.

ANGEL FOOD CAKE.

The art of making angel food cake consists first of all in beating the white of the egg until very light. Beating with a large wire whip is most satisfactory, but a mechanical beater may be used, though the cake is apt to be smaller, due to less air retained. The powdered or fine granulated sugar and pastry flour used in making angel cake are folded in carefully so as not to lose the air from the white. Once the art is learned, it is easy to make an angel food cake successfully if one can regulate the oven to a temperature not over 310°F., while the cake is being baked.

In angel food cake the addition of cream of tartar to the whites not only increases its power to stretch, and therefore make a larger bulk in beating, but also whitens the product and changes the flavor from decidedly alkaline to neutral, or slightly acid. Cream of tartar is always used in making angel food cake, though other powdered acids may be used. 1 cup egg white (average is 11 egg whites), 1 cup fine granulated sugar, $\frac{3}{4}$ cup cake flour (sifted 3 times before measuring), 1 teaspoon cream of tartar, $\frac{1}{4}$ teaspoon salt, $\frac{1}{4}$ teaspoon vanilla. Add salt and beat egg white on large platter, using flat wire whip. When foamy, add cream of tartar and beat with long steady strokes until mass is stiff and will form in heaps and ridges. Sift over the sugar, folding it in (not beating). Then sift over flour, folding it in gently. Place batter in unoled angel cake pan, keeping batter slightly higher at rim. Bake at 310°F. for about one hour. Invert in pan on wire rack until cold.

EGG WHITE DESSERTS.

Cold soufflés used for dessert are usually made with a gelatin foundation, into which the beaten whites of eggs are folded just as it begins to thicken. The product is then put into a mould to harden.

Fruit snows are made by folding the beaten whites of eggs into the cooked, seasoned, and pureed fruit, for example, prune whip, apple snow, peach, pineapple, or apricot snow. (If the fruit snow is to be given to children, it should be baked for 20 minutes. For adults it may be chilled.) Use one egg white to a half a cup of fruit for each person and serve with a soft custard made of $\frac{3}{4}$ cup of milk, 2 tablespoons sugar, salt, 2 eggs, and $\frac{1}{2}$ teaspoon vanilla.

HOT SOUFFLES.

Another use for egg white is in the various hot soufflés in which the basis is thick white sauce enriched with any of the following:—Grated cheese, spinach, dates, figs, meat, or vegetables. The yolk of the egg may be stirred into the warm sauce, or it may be omitted entirely. After the fruit, meat, or vegetable is put into the white sauce and mixed thoroughly, the beaten white of the egg is folded in and the product quickly put into an oiled casserole or other cooking dish and baked in a slow oven for 45 to 69 minutes. Soufflés so cooked must be served immediately, as they fall quickly. A soufflé foundation may be prepared at any time of the day and the whites folded in just before baking.

USES FOR EGG YOLKS.

Egg yolk may be used in the following ways:—Custards—soft, baked, fruit; golden angel food, chocolate sponge drops, date bars, and lemon pies; fried cakes and pan cakes; and noodles and soup garnishes.

Other uses are—

Boiled dressing and sauces.

Egg beverages—milk shakes and eggnogs.

Coating for croquettes with bread or cracker crumbs.

To enrich scrambled eggs or cream sauces.

To bind meat loaf or vegetable loaf.

Coating for bread in French toast.

CUSTARDS.

Custards are mixtures of eggs (whole or yolk only), milk, sugar, flavoring, and a pinch of salt. A general rule for custards is: 2 cups of milk, 2 large eggs or 5 to 6 yolks, $\frac{1}{2}$ cup of sugar, $\frac{1}{2}$ teaspoon salt, and flavoring. The sweetening, salt, and flavoring may be added to the yolks and beaten in as warmed (not hot) milk is added. Place custard mixture in dish, set dish in lukewarm water and bake in oven 300°F. until custard is just set or solid. The time varies with bulk and depth of mixture in custard cups or mould. Too long cooking or too high a temperature will spoil the texture or even cause the egg mixture to separate.

The "sweetening" of custard may be sugar, $\frac{1}{2}$ cup to a pint of milk, or $\frac{1}{2}$ cup maple syrup, or $\frac{1}{2}$ cup honey, or $\frac{1}{2}$ cup dark corn syrup.

FRUIT CUSTARDS.

Fruit custards are popular with children and most adults, although these custards tend to be over-sweet and rather cloying. Lemon juice is of value not only in giving better flavor to the fruit custard, but also in adding some vitamin C.

In these custards 1 egg yolk is used to $\frac{1}{2}$ cup of milk if the custard is to be eaten from the dish in which it is cooked. If it is to be turned from the mould, 1½ egg yolks should be used to every half cup of milk.

Bananas, dates, raisins, cooked prunes, and figs may be used. The sliced or cut fruit is put into the bottom of the mould, a few drops of lemon juice added to the fruit and the custard, made of $\frac{1}{2}$ cup of milk, 1 tablespoon sugar, 1 egg or 1½ egg yolks, and a few grains of salt, is poured over the fruit. This makes one serving. Beat the yolk slightly, add the sugar and salt, then the cold milk, and pour the fruit in the individual custard cup. Set the custard cup in warm water, the water coming up as high as the custard in the cup. Keep the oven temperature at 300°F., and when the custard is set, remove it, take it from the water and set in cold water or in a cold place to chill quickly. If a large number of custards are desired, multiply the quantity by the number to be served.

If the lemon juice is added to the milk and egg mixture, curdling may take place, but if it is added to the fruit, the fruit tends to absorb it sufficiently so that it does not affect the quality of the custard.

Golden Angel Food.—9 egg yolks, 1 cup sugar, 1½ cups cake flour (sifted once before measuring), $\frac{1}{2}$ cup water, 1 teaspoon baking powder, 1 teaspoon lemon flavoring, 1 teaspoon vanilla. Sift the flour and baking powder four times. Beat yolks until light and lemon colored, add sugar slowly, then the water and flour alternately. Add flavoring and bake in an ungreased angel food tin in a slow oven (300°F.) for 1 hour.

Chocolate Sponge Drops.—3 egg yolks, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup boiling water, 1 teaspoon vanilla, $\frac{3}{4}$ cup pastry flour (sifted with 1 teaspoon baking powder), $\frac{1}{2}$ teaspoon salt, 2 tablespoons cocoa. Beat egg yolks, gradually adding sugar. Continue beating until sugar is dissolved and eggs are lemon colored and thick. Gradually add boiling water and flavoring, mixing thoroughly. Fold in sifted dry ingredients. Drop by spoonfuls on ungreased cookie sheets and bake 15 minutes at 375°F. Ice lightly with chocolate icing.

Date Bars.—2 cups sugar, 1 cup butter, 10 or 11 egg yolks, $\frac{1}{2}$ cup cold water, 3 cups flour, 1½ lbs. dates, 1 cup nut meats. Cream butter and sugar. Beat egg yolks until light, and add water. Add this mixture to creamed sugar and butter, then fold in the flour, and beat well. Add stoned dates and nut meats, cut into not-too-small pieces. Bake in a slow oven until firm. When cool cut in bars and roll in powdered sugar. These will keep moist indefinitely in a covered metal or stone container.

Noodles.—1 egg yolk, $\frac{1}{2}$ teaspoon salt, flour. Beat egg slightly, add salt and flour enough to make very stiff dough. Knead, toss on slightly floured board

and roll paper thin. Cover with towel and set aside 20 minutes. Cut in thin slices. Dry, and when needed cook 20 minutes in boiling salted water, and add to clear soup.

Cheese Custard à la Royal.—2 egg yolks, 1½ tablespoons grated cheese, ½ cup milk, ½ teaspoon salt. Beat yolks of eggs. Add milk and salt, and strain custard into flat bottom pan. Add grated cheese and set in pan of hot water. Bake until set in oven of 350°F. Leave in pan until cold. Cut in fancy shapes. Place in soup bowl and pour over hot consommé and serve.

Hollandaise Sauce.—1 cup butter (½ lb.), 4 egg yolks, 2 tablespoons lemon juice, ½ teaspoon salt, ½ teaspoon cayenne, ½ cup boiling water. Warm butter, add yolks of eggs one at a time, beating thoroughly after each is added until mixture is thickened. Add lemon juice, salt, and cayenne, place in double boiler. Add water. Beat with a rotary beater until thickened. Serve over poached eggs.

Mayonnaise for Any Salad.—2 egg yolks, 1 teaspoon mustard, 1 teaspoon salt, ½ teaspoon pepper, 1 teaspoon sugar, 2 tablespoons lemon juice, 2 tablespoons vinegar, 1 cup oil or 1½ cups oil. Mix all dry ingredients into egg yolks, add the lemon juice and vinegar and beat. Add the oil slowly, beating with rotary beater steadily and slowly. The oil and egg should form a smooth mass in seven minutes. If the mayonnaise is to be used as decoration, add the larger amount of oil. This will keep in cold place for weeks. When using from the mass in the jar, leave the surface level.

Thousand Island Dressing.—1 cup mayonnaise, 1 tablespoon chopped chives, 1 tablespoon chopped pimiento, 1 tablespoon chopped green pepper, 4 tablespoons chili sauce, 1 teaspoon paprika. Stir carefully into the mayonnaise and serve at once on lettuce.

Boiled Dressing.—½ tablespoon salt, ½ tablespoon mustard, 3 tablespoons flour, 4 egg yolks (or 2 whole eggs), 3 tablespoons melted butter, 1½ cups milk, ½ cup vinegar. Mix dry ingredients; add eggs, butter, milk; cook over hot (not boiling) water; when it thickens, cool. If it gets too hot it will "curdle," but these lumps can be taken out if the mixture is beaten violently while still hot. When cool, add vinegar. The boiled dressing should be made, cooked, and cooled before the vinegar is added; then it will not affect the quality of the product.

BEVERAGES.

When the various beverages are enriched with beaten egg yolk their food value for children, adults, or for the sick is correspondingly enriched. There is also the advantage that the yolk may be taken raw or only slightly cooked.

Egg Lemonade.—(Serves two)—2 beaten egg yolks, juice of 2 lemons, ½ cup sugar, ½ teaspoon nutmeg, ice water—1 pint. Beat the sugar and egg yolks together. Add the lemon juice and nutmeg. Stir all together and add water. Serve with chipped ice.

Hot Eggnog.—2 egg yolks, 1 tablespoon sugar, ½ teaspoon vanilla, ½ teaspoon grated nutmeg, 1 cup hot milk. Beat yolks very light with the sugar; add the vanilla. Stir in the hot milk, pour into a glass, put grated nutmeg on the top and serve hot or cold.

Chocolate Eggnog.—1 teaspoon cocoa, 2 teaspoons sugar, 1 egg yolk, 1 cup hot milk. Mix cocoa and sugar and add to well-beaten yolk. Stir in the milk slowly, and serve hot or cold.

SUBSTITUTING YOLKS.

Yolks of eggs may be substituted in many recipes which call for whole eggs. Especially where high temperatures are necessary in cooking, as in fried cakes and pancakes, using the yolk of the egg makes a much more tender product than when the whole egg is used. This is due to the fact that the high cooking temperature toughens the egg white but not the yolk.

In using the yolks in this way, three yolks are substituted for each egg, and for each extra egg yolk used one teaspoon of fat is deducted from the amount of fat called for in the recipe. This is done because each egg yolk contains about 1 teaspoon of fat.

This recipe for fried cakes illustrates how a favorite recipe may be changed in this way. The original recipe called for 3 eggs and 7 teaspoons butter. Because the 6 extra egg yolks were used, however, 6 teaspoons butter were subtracted, so that the recipe now reads 9 egg yolks and 1 teaspoon butter.

Fried Cakes.—1 teaspoon butter, 1 cup sugar, 9 egg yolks, 1 cup milk, 4 teaspoons baking powder, $\frac{1}{4}$ teaspoon cinnamon, $\frac{1}{4}$ teaspoon grated nutmeg, $1\frac{1}{2}$ teaspoons salt, $3\frac{1}{2}$ cups flour. Warm butter and add half the sugar. Beat until creamy. Add remaining sugar to well-beaten egg yolks and combine mixtures. Add milk alternately with the flour, which has been mixed and sifted with baking powder, salt, and spices; more flour will probably need to be added to make dough stiff enough to roll. Cut and cook in deep fat.

USES FOR WHOLE EGGS.

SALADS.

There are many varieties of egg salads. One which always delights the children is sunflower salad, made by cutting the hard cooked egg lengthwise into four or five pieces, laying the whites on lettuce in the shape of a flower and using for the centre a mound of the grated yolk covered with mayonnaise. This really does look quite like a sunflower.

Instead of the grated egg yolk for the centre a mound of cottage cheese covered with mayonnaise is often acceptable. If the mayonnaise is not used, French dressing may be sprinkled over the petals of the sunflower and stoned dates and prunes may be used for centres.

A very good mixture for salad is chopped hard cooked egg, a little grated onion, and one-half as much chopped beets as there is egg. This, made into the shape of an egg and laid on a lettuce leaf, is very attractive. French dressing is good with it.

Japanese Salad.—(Serves two)— $\frac{1}{2}$ cup hot boiled rice, 2 hard boiled eggs, 1 slice of onion chopped, 1 slice of red pepper chopped, 1 slice of green pepper chopped, 1 sprig of parsley chopped. Put hot rice into a French dressing, toss carefully so grains do not stick together. Chop the egg whites and rice the yolks, add all the ingredients to the rice, chill thoroughly and serve on a platter of lettuce. Garnish with the parsley or with sardines.

Easter Salad.—Put eggs in upper part of double boiler and cover with boiling water. Put over lower part of double boiler which contains boiling water, cover, and let cook on range 35 minutes. Remove shells, and while hot hold between thumb and finger while pressing into apple shapes. Mix a bit of allowable vegetable color with cold water and apply to eggs, using a brush. Insert a clove to represent blossom end, and a stem and leaves to represent stem end (hot-house lilac leaves answer the purpose), and arrange on lettuce leaves. Serve with mayonnaise.

German Hot Slaw.—One small head cabbage, shred very fine. Put in saucepan with 2 tablespoons water, stir frequently, cook till tender, drain. Make following dressing:—2 eggs well beaten, $\frac{1}{3}$ cup vinegar, $\frac{3}{4}$ cup milk, 1 tablespoon butter, 2 tablespoons sugar, salt and pepper to taste. Combine ingredients, beating well. Turn over the cabbage and cook until dressing thickens. (*Recipes from Many Lands, compiled by Dorothy Ayers Loudon.*)

MAIN DISHES.

MAIN DISHES.

For breakfast and for lunch or supper the whole egg may be cooked in so many ways that its use answers the ever present problem of what to serve.

Combinations of egg and milk, egg and vegetables play their part from soup to dessert. The wise cook knows the temperatures which may be used to insure success and never fails to please with her egg cookery. Even her fried egg will not harm the most particular.

It is possible to cook an egg so that it has the flavor of a fried egg and yet is almost as digestible as a poached egg. This is done by melting a small amount of butter in a frying pan which has a close fitting cover. Slightly brown the butter. Drop in the eggs, add one teaspoon water, cover, and cook over a very slow fire. Enough steam will form to congeal the top of the egg so that it has an opaque appearance, and yet the bottom will be very tender.

SCRAMBLED EGGS.

To produce a light, tender, fluffy yellow mass of scrambled egg requires the cooking over water of the slightly beaten eggs, one to each person. Add one tablespoon whole milk, cream, or even hot water to each egg as they are beaten and cook slowly, stirring the mass away from the sides and bottom of the dish as the mixture cooks. Serve on toast and decorate with butter and paprika.

Scrambled Eggs with Bacon.—Cook in hot frying pan 2 half slices bacon to each person, keeping the pan tipped so the fat does not burn. As the bacon becomes crisp and brown, remove it to the warm platter. Set the frying pan away from the fire and put into it with the fat an egg for each person. Stir the mixture quickly to mix the eggs and fat and then cook gently over the fire until mass is soft. The fat prevents the mass hardening too much. Serve on toast with strips of bacon across each serving. This is excellent at picnics.

Scrambled Eggs (Japanese).—Break into frying pan half a dozen eggs, stirring lightly with knife. Add quickly, before egg begins to cook, a tablespoonful of chopped green pepper, the juice of an onion, half a cupful of chopped mushrooms, and a half a cupful of boiled rice. Toss all quickly together. Cook over a very slow fire, and serve hot.

Chinese-Japanese Cook Book by Sava Bosse Onoto Watanna.

Eggs St. George.—Heat crab flakes in cream with a slight seasoning of curry and paprika and mix them with scrambled eggs.

Scrambled Eggs with Peas.—Cut bacon into inch squares and cook crisp. Add slightly beaten eggs, two eggs to a person, and one cup peas to each eight eggs. Add seasoning to taste. Cook in frying pan over very low heat, stirring slowly until egg is thick. The fat prevents the egg from hardening and becoming a tough mass. This may be cooked over hot water, stirring the mixture until it is thick and creamy.

Scrambled Eggs and Cheese.—Scrambled eggs and cheese may be the main dish for your lunch, or can be successfully used as a filling for hot sandwiches. Scramble the eggs and when they barely begin to thicken, add grated cheese and continue stirring until the eggs are thick. The cheese will just melt, and that is enough. High temperature in cookery retards rather than aids digestibility of cheese. This is an easy way to use your small pieces of dry cheese.

POACHED EGGS.

To poach eggs, have ready a frying pan two-thirds full of boiling salted water, allowing $\frac{1}{2}$ tablespoon salt to 1 quart of water. Break 4 eggs one by one into a saucer and carefully slip them into the quart of water. The water should cover the eggs, and it should not be allowed to boil after the eggs have been put into it. When there is a film over the top and the white is firm, carefully remove the eggs with a buttered skimmer. Season with butter, salt, and pepper. Browned butter poured over the eggs adds flavor and attractiveness.

Carrots and Eggs.—Scrape and slice thin a bunch of carrots (2 cups). Melt butter in a stew pan. Add the sliced carrots. Cover with meat broth and cook

until tender—15 minutes. In this poach three eggs until nearly done. Then set aside to finish without added heat. Serve as luncheon dish. (*Belgian recipe.*)

Eggs a la Louisianne.—Poach an egg for each person. Leave them in water until needed. Fry circles of Canadian bacon or thin ham. Cut stale bread into circles, the size of the egg, and toast. Prepare a brown sauce—Spanish is best. Serve piled as follows:—Toast, meat, poached egg, covered with the sauce. Excellent luncheon dish.

Spanish Sauce.—3 tablespoons butter, 3 tablespoons chopped onion, 3 tablespoons chopped green peppers (may be omitted), 3 tablespoons flour, $\frac{1}{2}$ cup strained tomato, $\frac{1}{2}$ cup meat stock, $\frac{1}{4}$ teaspoon salt, $\frac{1}{4}$ teaspoon paprika. Cook onions and peppers slowly in hot butter until soft, add flour, and brown. Add tomatoes and stir until the mixture thickens. Season and serve over eggs. Chopped mushrooms may be added.

BOILED EGGS.

Remember that eggs need to be cooked at a low temperature; extreme heat toughens the white in eggs and causes them to be rubbery or leathery. Use $1\frac{1}{2}$ cups water to each egg. Heat water to boiling point. Add the fresh eggs to the water and place dish in warm place where temperature falls slowly. Ten minutes will give a soft cooked egg. Twenty minutes will give a medium hard egg. Forty-five will make the egg firm but not tough.

These eggs dropped in cold water will shell easily and may be used for creaming, as escalloped dishes and salads.

Eggs Mollet.—The eggs in the shell are first cooked as for soft boiled egg, cooled, carefully shelled and placed in cold water until needed. Before using them, warm gently in the water.

Eggs Duchesse.—Serve eggs mollet on flat oval shaped potato croquettes and pour over a cream sauce. Garnish with asparagus tips.

Eggs Mollet with Spinach.—Cook fresh spinach in waterless cooker five minutes. Chop it, mix it with cream and season with salt. Form it as a bed on which the eggs mollet are placed and surround with brown gravy.

Egg Barcelona.—Cut tomatoes in half. Broil in pan in oven and serve an egg mollet on each. Garnish with shredded green pepper lightly cooked in butter.

Eggs in Tomato Baskets.—Cut the tomato in halves, remove the seeds. Season with salt, pepper, and bits of butter, and bake in the oven. Fill with any flaked fish—crab, lobster, tuna, salmon—cooked in cream. Put the eggs mollet on top and cover with a cream sauce.

Scotch Eggs.—Use 2 hard boiled eggs, $\frac{1}{2}$ lb. uncooked sausage, and bread crumbs. Remove shells from eggs. Divide meat into two parts, place an egg in each part and mould sausage evenly over eggs. Roll in beaten egg, then bread crumbs. Fry in deep fat. Brown as doughnuts. Drain, then cut in halves. Serve surrounded by tomato sauce. (Equally good served on squares of toast.)

Recipes from Many Lands, compiled by Dorothy Ayers Loudon.

French Curried Eggs.—Take half a pound of onions, half a pound of tomatoes, one carrot, and two apples. Prepare these and cut into small pieces. Fry the onions first in butter until lightly brown. Add the other vegetables, putting some bacon fat into the pan. When these are nearly cooked put in one or two tablespoons of curry powder according to taste, adding sufficient salt, and two tablespoons of brown sugar. Fry for another half hour, adding more fat or butter if necessary. Just before pouring over the eggs which should, of course, be hard boiled first, add sufficient milk to the curry to reduce it to the consistency of a thick sauce.

A Second Helping, by X. Marcel Boulestin.

BAKED EGGS.

Soufflès are made with a thick white sauce foundation into which are mixed slightly beaten yolks and the finely divided food. The stiffly beaten whites are folded in last. The product is put into a buttered glass or porcelain mould and baked in a slow oven (325°F.) for 45 to 60 minutes. The soufflé must be served at once from the dish in which it is cooked.

Liver Soufflé.—(Serves four)—1 cup thick white sauce, 1 cup ground boiled liver, 2 egg yolks, 2 egg whites. *White Sauce:* 2 tablespoons butter, 4 tablespoons flour, $\frac{1}{2}$ teaspoon salt, $\frac{1}{2}$ teaspoon paprika, 1 cup milk. Prepare the sauce either directly over heat or in a double boiler. Cook thoroughly. Stir the ground liver and the yolks into the warm white sauce. Beat the whites until stiff and carefully fold them into the sauce mixture. Place in a buttered pudding mould so that it is half full. Cook one hour in a moderate oven. Serve at once in dish in which it is cooked.

Corn Custard.—1 cup canned cooked corn, $\frac{1}{2}$ cup milk, 2 tablespoons sugar, $\frac{1}{2}$ teaspoon salt, 1 egg beaten. Mix together and cook like a custard in the oven until egg thickens.

Spanish Loaf.—1lb. hamburger steak, $\frac{1}{2}$ lb. pork sausage, 2 eggs, 1 cup catsup, 6 crackers (rolled), salt, cayenne pepper. Mix and pack in baking dish. Bake one hour. This is fine cold.

Recipes from Many Lands compiled by Dorothy Ayers Loudon.

Scalloped Eggs.—Make a white sauce of 2 cups milk, $\frac{1}{2}$ cup sifted flour, $\frac{1}{2}$ cup butter, 1 teaspoon salt, and $\frac{1}{2}$ teaspoon pepper. Then add one tablespoon each of chopped parsley, pimienta, celery, onion, and green pepper and 1 cup of mushrooms which have been heated 5 minutes in 1 tablespoon butter. Pour this mixture over 8 hard boiled eggs and place in a buttered baking dish. Cover with buttered cracker or bread crumbs. Bake until thoroughly heated and brown on top.

Mexican Eggs.—(Serves six)—(1) 1 pint cooked tomato, $\frac{1}{2}$ onion chopped fine, $\frac{1}{2}$ cup butter. (2) 4 eggs, $\frac{1}{2}$ tablespoon paprika, $\frac{1}{2}$ tablespoon salt. Cook (1) together $\frac{1}{2}$ hour. Add this to the beaten eggs and seasonings, stirring them all the time. Continue to cook the mixture until it just thickens. Grated cheese may be added. Serve on toast.

DESSERTS.

The many kinds of custard, such as floating island, soft custard, baked custard, caramel custard are familiar to every housewife. Here are some further suggestions for egg desserts.

Rice Custard.—(Serves four)—Cook $\frac{1}{2}$ cup of cold cooked rice in 1 pint of hot milk until every grain is distinct, add yolks of 2 eggs, $\frac{1}{2}$ cup of maple syrup, a pinch of salt, and a teaspoon of vanilla. Cook a few minutes, turn into a baking dish, cover with a meringue made of two egg whites beaten stiff with two tablespoons sugar, brown slightly and serve cold.

Egg Soufflé.—(Serves six)—2 tablespoons butter, 2 tablespoons flour, 1 cup scalded milk, 1 cup scalded cream, 4 eggs, $\frac{1}{2}$ cup sugar, 1 teaspoon salt, $\frac{1}{2}$ teaspoon vanilla. Cream butter, add flour, and pour on milk and cream gradually. Cook in double boiler five minutes; add sugar and egg yolks beaten until thick and lemon-colored. Remove from fire, add seasonings, fold in egg whites beaten until stiff. Turn into buttered dish or individual moulds, set in pan of hot water, and bake in hot oven (350°F.) 45 to 60 minutes or until firm. Serve from baking dish.

Orange Omelet.—(Serves six to eight)—6 egg whites, $\frac{1}{2}$ teaspoon salt, 6 egg yolks, 2 tablespoons sugar, 2 tablespoons lemon juice, 4 tablespoons orange juice, $\frac{1}{2}$ teaspoon grated orange peel, 4 tablespoons butter. Beat the whites and salt until stiff. Beat the yolks until thick with the sugar and fruit juices. Fold these

into the whites one third at a time, so as to retain the air. Melt the butter in a large omelet pan. Pour in the omelet mixture and put in a slow oven for 20 minutes. Fold on platter. Serve at once.

Cottage Cheese Torte.—(Serves six)— $2\frac{1}{2}$ cups toasted bread crumbs, 1 cup sugar, 1 teaspoon cinnamon, $\frac{1}{2}$ cup butter (melted), 4 eggs, 1 cup sugar, $\frac{1}{2}$ teaspoon salt, $\frac{1}{2}$ lemon (juice and grated yellow rind), 1 cup cream, $1\frac{1}{2}$ lbs. cottage cheese, $\frac{1}{2}$ cup flour, $\frac{1}{2}$ cup nuts chopped. Mix crumbs, sugar, cinnamon, and the melted butter. Set aside $\frac{3}{4}$ cup of the mixture to sprinkle over top. Butter a 9in. mould, spread mixture over the bottom and sides of the mould. Beat the eggs together with the sugar until light; add salt, lemon juice, and grated rind. Then add the cream, cheese, and flour. Mix these well and strain through a sieve. Again stir the mixture and pour it into the lined mould. Sprinkle the $\frac{3}{4}$ cup crumb mixture and the nuts over the top. Bake in a moderate oven 1 hour. Then turn off the heat and let the torte stand in the oven 1 hour to cool slowly.

German Blitz Torte.— $\frac{1}{2}$ cup butter, 4 egg yolks, 1 cup flour, $\frac{1}{2}$ cup sugar, 4 table-spoons milk, 1 teaspoon baking powder. Mix as for cake and bake in two layers. Cover with following: 4 egg whites beaten stiff and mixed with 1 cup powdered sugar. Add cocoanut or fine nuts before putting on meringue. Bake 30 minutes in slow oven. Put together with whipped cream, fruit or custard filling.

Recipes from Many Lands compiled by Dorothy Ayers Loudon.

Lemon Cheese Cakes.—Melt $\frac{1}{2}$ cup butter in a double boiler, add 2 cups granulated sugar, 6 eggs, well beaten, and the grated rind and juice of 3 lemons. Stir until it is the consistency of thick cream. Line patty tins or shallow gem pans with a light crust, rolled very thin. Fill with lemon cheese, and bake in a fairly quick oven. The lemon cheese may be poured into glasses and sealed. It will keep good for months, and makes a fine spread for thin slices of bread or wafers.

Old English Recipe.

Custard Fruit Pie.—1 pastry shell baked, 3 eggs, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ teaspoon salt, 2 cups milk, 2 cups halved sweetened strawberries or other fruit, $\frac{1}{2}$ cup whipping cream. Scald milk in double boiler. Beat eggs slightly, add sugar and salt, and add gradually to milk, stirring constantly. Add the fruit, and pour into pastry shell and bake 30 minutes in slow oven. Just before serving spread whipped cream over the top of pie.

BALHANNAH.

January 17th.—Attendance, 14.

SAUSAGE-MAKING.—Paper read by Mrs. H. Spoehr:—“Place the cut-up pig’s head, liver, and heart in water overnight, put in the water one handful of salt to take out all blood. Next morning, put pieces on to boil in a large boiler or copper, also all spare rinds and a piece off the bacon 2ins. wide on the bottom side. When tender, lift meat out to cool. *White Pudding.*—Mince liver and all the fattest parts, no rinds, add salt and pepper to taste, a few caraway seeds and marjoram, also boil four onions in a saucepan with some of the stock in which the meat was boiled. Strain through a colander into the minced meat, add enough stock to enable it to be filled into the casings and tie well. Then put the sausages into the stock until cooked. They must not boil or they will burst. Have a table ready covered with white paper, lift sausage out carefully, and dip it into a dish of cold water and then lay it on the table to cool. *Dark Pudding.*—Mince all rinds and a little of the cooked pork and heart. Have ready about 8lbs. of rice soaked overnight in a jam pan. In the morning pour off the water and then cover rice with the stock in which the meat was boiled, add a handful of salt and boil until tender, then take off the fire and stand to cool. Add the rice to the minced meat, also pepper, salt, marjoram, a little ground allspice to taste, blood to make it moist and dark. Put into the casings, tie tightly, and cook same way as white pudding. Try with a hatpin; if red shows they must stay in until clear fat comes out, then lift out and treat same as white pudding. When cold and set they can be hung up in the smokehouse and smoked for a day or two to give them a smoky taste, or hung in a cool dry place. *Metwurst.*—25lbs. meat, 14ozs. salt, $\frac{1}{2}$ oz. saltpetre,

3ozs. white pepper, 1lb. white sugar. Mince a shoulder of pork weighing 16lbs. and 9lbs. of tender red beef. Then put through the mincer, add all the ingredients, and mince again. Mix thoroughly, then hang in smoke room and smoke gently for eight days.

February 23rd.—Attendance, 27.

JAM MAKING.—Paper read by Mrs. F. Leane—"Rule for jam making vary slightly for different fruits, because all do not contain the same proportion of pectin and acid, which helps to dissolve the pectin. Fruits low in pectin may have lemons or acid fruits added. Over-ripe fruit is unsuitable, it contains little pectin, and is not likely to keep so well. Sound and dry fruit is essential, and it must be free from dust. Insufficient cooking is often the cause of failure, and mould on the jam is the result. The object in cooking is to evaporate the water in the fruit. If insufficiently cooked the jam will not set, and if overcooked the jellying properties are destroyed and the color is spoiled and alters the flavor. Whether jam should boil quickly or simmer is much disputed. Candy on the top of jam is caused by the jam being brought to the boil too quickly after the sugar is added, it should be brought slowly to boiling point and then boil briskly until done. Apricots and figs are preferred by some to have sugar put on fruit over night, it keeps the fruit from breaking and makes more of a conserve. Berry fruits are best brought to the boil and sugar added afterwards. The usual proportions are 1lb. sugar to 1lb. fruit, but acid fruits, such as certain varieties of plums and quinces, often require 1lb. sugar to 1lb. of fruit. Berry fruits and marmalade should be allowed to cool before bottling, the heat drives the berries and light shreds to the top, leaving a gap of clear syrup. When mixing fruit, such as blackberry and apple, and blackberry and plum, it is best to boil each fruit separately until soft, then mix; if boiled together the fruit remains hard and will not mash. Brewers crystals are often used in preference to ordinary sugar. To make jelly successfully, boil the fruit slowly and thoroughly, strain through a jelly bag, and on no account squeeze nor wring bag, or the jelly will not be clear. Measure the juice and bring to the boil before adding sugar, which is usually 1 cup of sugar to one of juice. Boil for about 20 to 30 minutes and then test a little in a saucer. If the sample is cooked it will jell and wrinkle when lifted with a spoon. Care should be taken when bottling jam—make sure that the jars are clean and dry, if the jars are damp it will cause a ferment. There are various ways of sealing jam. Paraffin wax is very good; clag is another good paste, also boiled starch. Mice will not touch either of these two pastes mentioned." (Secretary, Miss D. Spoehr.)

KYBYBOLITE (Average annual rainfall, 22in.).

December 5th.—Attendance, 34.

HOME-MADE CONFECTIONERY.—Mrs. G. Davidge read the following paper:—"In addition to recipes it is necessary to learn to adapt any formula to one's own requirements, and to do this, close application to the subject and careful observation of the different results obtained are required. Great care must be exercised with heat, in order not to scorch the syrup before the proper degree of boiling has been registered. If making large quantities of sweets, have a marble slab to work the sweets upon, and also for pouring the confections. Failing this, enamel dishes turned upside down, and damped with cold water, are quite satisfactory, or sandwich tins well buttered for toffee or butterscotch. These must be cut into squares before the toffee is quite cold. No butter is ever used on the slab or dishes for cream confections. Do not attempt any recipe until quite conversant with all details, especially the degree of boiling. A thermometer and maize syrup are the secrets of successful confectionery; sugar is boiled to various degrees with the thermometer, more or less according to the kind of sweets being made. Watch the degree carefully and only take it to the number stated in the recipe, then remove from the fire immediately. After a little careful experimenting it will soon be possible to handle the thermometer in an expert manner. Handle this article with great care in order not to break it. Keep the thermometer scrupulously clean, because if placed in any syrup with the previous boiling sticking to it, the whole mass will probably be spoilt. Success in sweet-making depends on strict attention to this and similar small details. Fondant is one of the first foundations in the making of many kinds of sweets; great care should be taken with this, it will require both patience and care. Success depends entirely upon boiling the sugar to the exact degree; the heat should be strong and steady, but not too intense. In making up very small batches of sugar, such as 1lb., it is sometimes difficult to get the thermometer to register correctly on account of the fact that it will not go deep enough down in the syrup. During the boiling process stirring must only be done when specified, as this is likely to granulate the batch, causing it to

become hard and revert to sugar. Fondant made of sugar and cream of tartar produces a firm and smooth cream, and is the purest. *Recipe for Fondant Products.*—Place 1½ lbs. of sugar, a scant teaspoonful of cream of tartar, and about a pint of water in a clean saucepan. Set on the stove and stir with a wooden spoon until the sugar is thoroughly dissolved. When it comes to a boil skim off all foreign matter carefully, place lid on saucepan, and allow to boil two or three minutes. Remove lid and insert thermometer, which should be in a jug of warm water near the stove. When it registers 240 degrees remove instantly from the fire, leave until lukewarm, then start the creaming process. Stir well with a wooden spoon. It will turn cloudy and become quite thick. Wring out a cloth in cold water and place it over top of fondant. Leave for half-hour or more and it will then become mellow. Scrape and mash down well, knead with the hands, which have been dipped in cold water; knead on a marble slab if possible. It is now soft and creamy and can be moulded into different shapes and colors. Chopped nuts may be added for variety. They can be dipped in chocolate, and almonds, walnuts, raisins, &c., placed on them. *Recipes for Coconut Ice or Swiss Cream.*—3½ lbs. sugar, ½ lb. maize syrup, moisten with water, and place on the fire, stir until dissolved, then put lid on saucepan for a few minutes to get all the sugar steamed off the side of saucepan. Take off lid and place thermometer; when it registers 240 degrees remove from fire and beat, gradually adding 1 lb. of fine cocoanut. When a thick heavy cream, pour on marble slab or enamel plate. Color some pink to make a variety. If Swiss cream is desired use flaked cocoanut instead of the fine. *Snowballs.*—Soak 2 ozs. gelatine in 2 cups of water for two hours, add 2 cups of hot water, and 2 lbs. of white sugar; boil 20 minutes. Allow to cool, add 1 teaspoon vanilla, then beat with a egg-beater until firm and frothy and it will not turn back into jelly. Pour into dishes and leave for several hours, then cut into squares, dip in chocolate, and add small decorations. They can be varied with different colors. Cocoanut can also be toasted on the oven slide in a slow oven until a light brown, then roll some in this, calling them toasted marshmallows. *Serbian Rock.*—2½ lbs. sugar, 1½ lbs. maize syrup, water to dissolve same. Boil to 255 degrees, then remove from fire, beat, and when cool, add stiffly-beaten whites of two eggs, then beat hard, adding nuts that have been cut into small pieces. When getting fairly stiff, pour on marble slab, then when quite cold, break into small pieces. This can be colored different shades, but keep the colorings pale, as this will make the sweets more tempting. *Clear Toffee Recipe.*—2 lbs. sugar, ½ lb. maize syrup, moisten and place on fire, bring quickly to boiling point—212 degrees. Put lid on saucepan, and steam down sides of saucepan, then remove lid, place in thermometer, and boil very quickly until 310 degrees. Pour into buttered tins and cut up when cold. The same recipe is used for butterscotch, but when it is removed from the fire, add 3 ozs. of butter and stir it in well with nuts or cocoanut. Always keep butterscotch and toffee in an airtight tin.” (Secretary, Mrs. Kekwick.)

McLAREN FLAT.

February 1st.—Attendance, 17.

SCONES AND PASTIES.—Recipes supplied by Mrs. J. Smith:—When making scones, use a large shallow dish to give plenty of room for mixing. Do not stir the mixture, this makes the scones heavy. Small quantities do not turn out as well as larger ones. Care must be taken not to mix the dough too stiffly, the mixture should be fairly moist and just dry enough to be cut with a knife. It is better to cut scones with a knife, a round cutter leaves odd pieces, which have to be rolled out again, and these are not so light because of the second handling. The less scones are handled the lighter they are. When using thick milk for mixing, always beat well first. Milk is generally used for glazing, but scones are much lighter if left unglazed. Test the oven with a piece of kitchen paper, which should turn a dark brown in 30 seconds. *Plain Scones.*—Take 1 lb. S.R. flour, 3 ozs. butter, ½ teaspoon salt, ½ pint milk, 1 teaspoon icing sugar. Method.—Sift sugar with flour, add salt, rub in butter lightly with fingertips, make hole in centre and pour in milk. Mix together very quickly, turn on to floured board, fold edges under with sides of the hands—not the fingers—press out and cut into desired shapes. Cook at once in a very hot oven from 5 to 10 minutes. *Gem Scones.*—Two cups S.R. flour, 1 cup milk, pinch salt, 1 egg, 2 dessertspoons butter, 2 dessertspoons sugar. Method.—Sift flour and salt; rub in butter lightly; beat egg and sugar together, adding milk; add these to the flour, &c.; beat well until smooth. Place a dessertspoonful in hot greased gem irons. Bake in a very hot oven for 10 minutes. *Cornish Pasties.*—To make good Cornish pasties the choicest beef should be chosen. The same applies to the vegetables, which need to be young and fresh. If coarse meat or old vegetables are used they require longer cooking, resulting in dry, indigestible pasties. Take ½ lb. steak, 4 ozs. potatoes, 1 large onion, 1 teaspoon salt, ½ teaspoon pepper, ½ lb. short crust. Method.—Remove fat and skin from meat and

cut very finely, also onion and potato and add to meat. Mix well with pepper and salt, and divide into 8 equal parts. Make short crust and divide this also into 8 equal parts; form each piece into a ball and roll as round as possible and about 6in. in diameter, trim the edges neatly. Place the divided mixture on to each round of pastry, brush half way round each piece with cold water, fold the two edges together and press well, then make a neat frill by placing the first finger of the left hand on the rim of the pastry and pinching with the thumb and first finger of the right hand. Place on a cold greased dish or oven slide, brush over with yolk of egg, and prick with a fork. Cook in a hot oven from 30 to 40 minutes. Garnish lightly with parsley and serve on a hot dish with brown sauce or tomato sauce. A point to be avoided is over-garnishing, just one small piece of parsley is sufficient for each pasty. It is important to have the oven very hot. (Secretary, Mrs. D. Elliott.)

MILLICENT (Average annual rainfall, 29.8in.).

February 16th.—Attendance, 11.

RECIPES FOR PEARS AND QUINCES.—Mrs. Cassells: *Pear Preserve No. 1*.—6lbs. pears, 3lbs. sugar, 4ozs. whole ginger (bruised), $\frac{1}{2}$ pint of vinegar. Boil all together until red and clear. *Pear Preserve No. 2*.—2 $\frac{1}{2}$ lbs. pears, 2 $\frac{1}{2}$ lbs. sugar, $\frac{1}{2}$ pint of vinegar; add cloves and cinnamon to taste. Boil all together until clear and a good color. *Pear Preserve No. 3*.—6lbs. pears, 4lbs. sugar, $\frac{1}{2}$ lb. green ginger, 1 cup of water. Pare and quarter the pears; stand in sugar and water all night, add ginger, and boil until clear. Mrs. Ey: 8 large quinces, 5lbs. sugar, 2 $\frac{1}{2}$ cups water; grate the quinces, boil sugar and water together, skim, add grated quinces; boil for 20 minutes and skim if required. Miss Kath. Hutchesson: *Quince Marmalade*.—To each pound of fruit allow 1 cup of sugar. Boil and core quinces and cut fruit into dice. Cover peel and seeds with water, boil one hour, strain, add sugar, and put on to boil. When boiling, add fruit and boil from 1 to 2 hours. *Quince Honey*.—Take 10 cups of sugar, 2 pints of water, and 6 large quinces. Boil sugar and water about 20 minutes, then add grated quinces; boil until a nice color, and the thickness of honey. Mrs. J. M. N. Altschwager: *Quince Marmalade*.—Cut quinces into dice, and to every 1lb. of fruit allow 1 pint of water and 1lb. of sugar. Boil cores and peel separately in water; strain and pour over the sugar. Boil syrup 30 minutes, then add fruit and continue boiling until a deep rich red and the liquid jells when tested. *Preserved Quinces*.—12lbs. quinces, peeled, cored, and quartered, 4lbs. sugar, 1 cup water, 2 cups white wine vinegar, 2ozs. cinnamon bark, $\frac{1}{2}$ oz. cloves. Boil water, vinegar, sugar, cinnamon, and cloves for a few minutes; then put enough quinces in just to cover the bottom of the pan; remove when soft and bottle. When all are cooked, if there is not enough syrup to cover the fruit, make some fresh syrup in the same proportions. *Quince Jelly*.—Cut quinces into quarters, use peel and pips; cover with water and stew gently; do not allow fruit to mash. Use green quinces fully grown, strain and measure, and return to pan. As soon as it boils add cup for cup of sugar, boil rapidly until it will jelly. Mrs. A. Bryant: *Preserved Fruits*.—Take 6lbs. sugar, 12lbs. quinces, pears, or figs, 1 $\frac{1}{2}$ pints vinegar, 1oz. each cloves, allspice, and whole ginger (boiled in muslin bag). Put vinegar and sugar on to boil with spices and just as it is boiling drop in fruits, peeled and cored (figs whole), and boil about 1 hour until the syrup thickens a little and the fruit is tender and nice color. Mrs. H. J. Hutchesson: *Quince Jam*.—To every pound of peeled and cored quinces use $\frac{1}{2}$ lb. sugar. Boil the peels and cores until tender, then strain. To every 4 cups of juice add 3 cups of sugar. Pour over cut or minced quinces and boil until it will set. *Pear Jam*.—12lbs. pears cut into rather large pieces, 9lbs. sugar, 4 $\frac{1}{2}$ pints water, 1 tablespoonful cloves, 1 teaspoonful citric or tartaric acid. Boil sugar and water together for $\frac{1}{2}$ hour, add fruit, and boil for 4 or 5 hours or until it turns red. The cloves must be tied with muslin and boiled with jam. A small quantity may be used if liked. Add acid about 20 minutes before it is done. (Secretary, Mrs. M. Hutchesson.)

TANTANOOLA.

February 7th.—Attendance, 10.

BOTTLING FRUIT.—Mrs. Edgecombe read the following paper:—"The fruit should be ripe but firm, and of even size. If peaches and pears have to be peeled, drop them into cold water to prevent discoloring; pack very tightly in bottles, fill with cold syrup, and leave a few moments for the syrup to soak into fruit. Then screw on lids—for Mason bottles—not too tightly, put in copper, kerosene tin, or any other vessel that has a good fitting lid. Bring to almost boiling point and maintain at that for about $\frac{1}{2}$ hour or until fruit is cooked. Take from tin and screw lids down tightly. To preserve with a Fowler's outfit, the process is much the same, there being a steriliser and thermometer instead of a tin. Fill the bottles as full as possible, fit the rubber

ring, fill with cold syrup, put lid on and clip down. Place in steriliser and continue until full, and place on fire; bring to required heat and keep at same until cooked. Mason's and Fowler's bottles can be done at the same time in the steriliser. The syrup I use is 1lb. sugar to 1 qt. water, and the cost of sugar is about 1d. a bottle, so that if the fruit is a reasonable price, or any one has their own fruit, the cost is very little. I use the rubber rings more than once, but they must be sound. I find apricots the hardest of all fruits to preserve for appearance, as they are apt to rise in the bottles and will not stand so much rough handling as other fruit." (Secretary Mrs. Telfer.)

WASLEYS.

February 1st.—Attendance, 24.

RECIPES.—Miss G. George contributed the following:—*Shortbread Tart*.— $\frac{1}{2}$ lb. S.R. flour, 4ozs. each butter and sugar, 1 egg, essence lemon. Beat butter and sugar to cream, add egg and flour, roll thinly, and bake in pattypans. *Lemon Filling*.—1 tablespoon each cornflour and custard powder, 1 cup hot water, $\frac{3}{4}$ cup sugar. Put sugar and water on to boil and thicken with cornflour and custard powder mixed with juice of lemon. Mrs. W. O. Toll supplied the following:—*Plum Sauce*.—6lbs. plums, 6 cups vinegar, 3lbs. sugar, 6 teaspoons salt, 1 teaspoon white pepper, 1 handful each whole ginger and cloves, 2 large onions; boil one hour then strain. *Worcester Sauce*.—2 quarts vinegar, 1 $\frac{1}{2}$ ozs. each onions and eschalots, $\frac{1}{2}$ oz. each mace, black pepper, cloves, cayenne, 1 pint Indian soy; put in a jar and shake every day. *Genoa Cake*.—1lb. each butter and sugar, 1lb. 3ozs. plain flour, $\frac{1}{2}$ lb. chopped peel, 1lb. each raisins, sultanas, and currants, 1 teaspoon each spice and grated nutmeg, $\frac{1}{2}$ lb. each blanched almonds, dry figs, and crystallized cherries, small glass brandy or sherry, small $\frac{1}{2}$ teaspoon baking powder. Clean and dry fruit the day before. Cream butter and sugar, add eggs one at a time, and beat well; add fruit and sifted flour alternately. Icing: $\frac{1}{2}$ lb. almond meal, 1 white of egg, $\frac{1}{2}$ lb. icing sugar, few drops almond essence; mix icing sugar and almond meal to flour with whipped white of egg, then stir over fire until warm and stiff enough to roll out; sift icing sugar on to board to roll and make size of cake, and pat on to top of cake. Ice and decorate in the ordinary way. *Tomato Sauce*.—12lbs. tomatoes, $\frac{1}{2}$ lb. salt, 1oz. each cloves, whole spice, and peppercorns, $\frac{1}{2}$ oz. bruised ginger, $\frac{1}{2}$ oz. each mace and garlic, 1lb. onions, 2lbs. sugar, 3lbs. apples, 2 pints vinegar. Put all on to boil (except vinegar) for two hours, then strain and put back with vinegar and boil until thickness of cream. Miss G. Smith: *Blow-away Sponge*.—4 eggs, $\frac{3}{4}$ cup sugar $\frac{1}{2}$ cup cornflour 2 teaspoons plain flour, 1 level teaspoon cream of tartar, $\frac{1}{2}$ teaspoon soda. Beat whites of eggs with knife until stiff, add sugar, and beat until dissolved; add yolks and beat five minutes; add sifted flour and rising and beat in, still using knife; do not stir, put into sandwich tins, bake in hot oven 7 to 10 minutes. Miss V. Currie: *Cucumber Pickle*.—Cut up 4lbs. each green tomatoes, cucumbers, and onions, 2lbs. beans; do not peel cucumbers. Pour over brine made of 4 quarts cold water and 1lb. salt; stand all night. Put on to boil and boil for five minutes. Lift off and strain well. Boil 1gall. vinegar with 2 teaspoons ground allspice; when it boils stir in the following ingredients, well mixed:—5 cups sugar, 2 cups plain flour or cornflour, 1 $\frac{1}{2}$ tablespoons tumeric, 2 teaspoons white pepper, 2 tablespoons each curry powder and mustard; mix to a paste with 3 cups cold water. Stir well into vinegar, bring to boil, put in the pickles, leave until nearly cold, then bottle and cork well. Mrs. L. C. Teakle: *Tomato Sauce*.—12lbs. tomatoes, 1oz. garlic, 2lbs. onions, $\frac{1}{2}$ oz. ground ginger, $\frac{1}{2}$ lb. salt, 1 teaspoon cayenne, $\frac{1}{2}$ teaspoon cloves (tied in muslin), $\frac{1}{2}$ lb. sugar, 1 quart vinegar. Skin the tomatoes and onions, slice, and boil with cloves until soft; stir well. Press through a colander. Add other ingredients and boil smartly for one hour until right consistency. Stir well with a wooden spoon. When done, pour at once into an earthenware dish, and bottle when cold. Cork well and it will keep for years. An enamelled pot is the best to use. Mrs. J. Mullen: *Three-minute Sponge*.—1 small cup sugar, 1 tablespoon milk, 3 tablespoons melted butter, 3 eggs, 1 large cup flour. Beat all together for three minutes, then add 1 teaspoon cream tartar and $\frac{1}{2}$ teaspoon soda. Miss J. Braun: *Crunchies*.— $\frac{1}{2}$ lb. butter, 1 cup sugar, 2 eggs, 1 cup cocoanut, 5 cups cornflakes, vanilla essence. Cream butter and sugar, beat in the eggs, then add cocoanut and cornflakes and essence; mix well, and drop small spoonful on tray. Bake in moderate oven for about 30 minutes. (Secretary, Miss J. Braun.)

CONFERENCE AT RIVERTON.

Delegates from the Women's Branches situated in the Lower North districts met in Conference at Riverton on February 22nd. Mrs. W. C. Johnston presided over an excellent attendance. The following papers were read:—

KNITTING.

[By Miss VERA GILLEN, Clare.],

Knitting, as well as being a useful occupation, is a pleasant recreation. Many dainty and serviceable garments, &c., can be made for a small outlay. When commencing an article be sure and procure enough wool; it is better to have a little over than not enough to finish the article.

There is always a certain amount of difficulty and uncertainty in producing the exact size of garment at which one aims. One worker knits loosely, another tightly, and the tension of the work varies accordingly, and though given instructions may have been followed stitch for stitch, there is disappointment when the piece of knitting turns out to be larger or smaller than was intended.

This difficulty may be avoided by making it a rule always to start with a specimen of knitting before beginning the actual piece. Cast on 24 or 30 stitches with the prescribed wool and needles, and knit a dozen rows or so. Then measure how many stitches go to the horizontal inch and how many to the upright inch. It will then be perfectly simple to determine by a rapid calculation the exact size to which the knitting will work out.

Another point is to make sure that wool and needles suit one another. Here again a sample piece of work is the only safe and reliable test. These two points take a little extra time, but it will be time well spent.

Work into the back of cast-on stitches. This gives a firm edge. When casting-off, do it on the wrong side; this also gives a firm edge. Garter stitch is plain knitting. A "ridge" or "rib" is two rows of plain knitting. Plain smooth fabric is one row plain and one row purl.

Knitting in pattern requires more thought than plain work, but the stitches are the same. There are only two plain and purl; it is the way you place them that makes a pattern. To make a stitch one way is to knit into the front, then into the back of a stitch. Another way is to place the wool forward before knitting the next stitch. To decrease, knit two stitches together, or knit two stitches and pass the first stitch over the second stitch.

To join wool, take a darning needle and work one strand into the other, or splice the wool; moisten with a little water, lay strands together and rub gently between the fingers. Always try to have the join at the beginning of a row; it will not show so much as in the middle of a row. *Never* knot the wool; as well as being untidy, the knot often gives way, causing stitches to drop. When commencing a row, always slip the first stitch, or, alternatively, knit into the back of the stitch; either way gives an even edge and makes it easy to join. If shoulder-seams are grafted together they are much neater.

Always buy wool of the best quality; poor quality wool does not wear or wash so well. Fine wools and fine needles are best used in knitting baby's woolies. Sports wool, in addition to being used for jumpers and pullovers, makes excellent cot and pram covers when knitted on large needles (size 4 or 3).

The pressing of the finished article is most important; it should be pinned to the exact measurements on to the ironing blanket and pressed with a damp cloth and warm iron. Fancy knitting is best pressed on a thick towel—the towel keeps the pattern from going flat.

Care should be taken in putting the knitted article together; see that each seam corresponds with the other. Before sewing with the machine it is a good idea to join the seams with wool. Be sure that all loose ends of wool are neatly fastened. The neatness of the finishing is just as important as the evenness of the knitting.

ITEMS OF INTEREST TO THE HOUSEWIFE.

[By Mrs. H. C. NIELD, Wasleys.]

The duties of a housewife are liable to become very monotonous, therefore it is necessary to consider the easiest and most interesting methods.

COOKING HINTS.

When dressing poultry—if the bird is scalded in boiling water then wrapped up for a few minutes in several thicknesses of newspaper, the task of plucking the feathers will be a simple one. There is a danger of roast poultry, particularly fowl, becoming dry; this may be overcome by placing the dressed bird in a paper bag to roast in the usual way. I prefer to put all roasting joints into a hot oven and decrease the heat over the last cooking period.

Milk puddings and baked custards are very nourishing. If the pudding-dish is placed in a larger dish containing hot water and baked in a moderate oven, the pudding will set evenly and light without curdle, and the custard will be all that can be desired. When cooking rhubarb, this method can be adopted, and if the dish is covered, the rhubarb remains in dice as it is cut and the full flavor is retained. Slices of lemon or orange added to stewed rhubarb further improve the flavor. Gelatine added to stewed cherries, apricots, or prunes makes a good summer dish, especially for picnics. Any of these fruits set in small pots, such as 4oz. marmite jars, make an appetising school lunch for children. Cornflour added to the juice of stewed fruit is an improvement to plums and apricots.

Baked apples and pears are improved by placing a date in the centre after the core has been removed. Pears should be green for baking—late varieties for preference. I half-fill the baking dish with water when baking these fruits.

When cooking cakes or sponges, place a slide on top. To remove a cake from the tin, first place on a damp cloth and there is no danger of the cake sticking to the tin.

Bread for toast placed in the oven for a few minutes improves the flavor and requires very little heat to brown.

Before boiling milk, first put a little cold water in the saucepan. This prevents burning. To make the washing of the milk saucepan easier, turn the saucepan upside down immediately it has been emptied. In the case of a burnt saucepan, add a handful of salt, fill with water, and place on the fire to boil. Empty the water and put saucepan in the sun for a time. Salt also removes milk or fruit juice from the top of the stove or the oven, if inadvertently it boils over.

During summer, the care of milk and cream is an important factor. Milk should be kept in wide-top jugs—not enamel; and both milk and cream should be cooled as quickly as possible. The task of making butter during hot weather becomes simple if the cream for churning is hung outside in a damp calico bag overnight. Place a pan or bucket under bag to catch the drippings. This is suitable only for household purposes, churning enough cream for 2lbs. of butter. Churning should be done early next morning. A rubber dish-scraper is very useful for scraping all cream dishes and cans, and can be purchased for a few pence.

WASHING AND CLEANING HINTS.

Rainwater gives the best results in the laundry, but if ever compelled to use hard water, Lux added to the copper is an improvement. A cup of fresh milk added to the bluewater prevents streaks of blue on the clothes. These hints greatly minimise the disadvantage of hard water. A very useful article in the laundry is a drain-box; this can be made from a kerosene case with the lid on, opened on one side with holes bored for drainage. Put rope handles at each end and place over a tub to drain; this is much cheaper and more durable than a basket.

To prevent a skin forming on starch, cover bowl with a cloth. This also applies to boiled custard.

The problem of spring-cleaning can often be lightened by using easy methods. A stiff clothes brush is excellent for seagrass furniture. Oak furniture needs much care, but can be easily restored with various furniture polishes. Boiled linseed oil, vinegar and methylated spirits mixed together is a good polish. Vinegar or methylated spirits added to the water when washing windows and mirrors will improve the finish. Turpentine added to stove polish lightens the work and a much brighter polish will result. The backs of pictures, interior of wardrobes and drawers should be periodically painted with turpentine, to prevent silverfish and moths. Aluminium and copper kettles clean easier when hot.

To prevent dust when sweeping a carpet or dusty boards—not polished—place small pieces of damp paper on the carpet or floor. A cloth sprinkled with methylated spirits will brighten hearthstones and grates.

Eucalyptus is a valuable cleaner in many ways; coat collars, marks on suits and frocks can be safely sponged, and black grease will quickly vanish from silk or other fine fabrics. Navy serge is easily cleaned with a strong solution of blue and hot water. Warm flour is an economical cleaner for cream serge, white felt hats, or woollen fabrics. This is not very successful for deep-seated marks.

The difficulty experienced of threading the machine needle is overcome by placing a piece of white paper or cloth under the needle.

The knee of a man's trousers can be patched without bother by opening the leg seam. Old lisle or silkesta stockings are excellent dusters after the feet are past mending. Two stockings opened and stitched together are good; three are even better.

Every mother dislikes the look of crust on baby's head. This can be prevented by sprinkling a little borax on the flannel each morning when washing the head.

During summer small black ants become very troublesome, and a good exterminator is found in this recipe:—1 cup sugar, $\frac{1}{2}$ cup water, 1 good teaspoon borax; boil for five minutes. Place in flat tins and the ants will feast on this and then disappear for weeks or perhaps months.

When washing jam bottles after filling, use cold water; this is easier to use and just as effective.

NEEDLEWORK.

[By Misses S. and L. BLIGHT, Clare.]

Doing fancy work is a gift as well as an art and it is also a very pleasant pastime during winter evenings. Procure the best traced linens, also the best of silks, cottons, and crochet cotton. Semco linens and cottons are recommended, also D.M.C. colored stranded silk. Clarks' stranded is very harshly toned and is difficult to blend in the colors, and if one does not have a good blend the work is not nearly so attractive. We mostly use for our work Semco linen, D.M.C. stranded, and No. 12 Semco crochet cotton. To make a nice supper cloth, choose a good linen with a bold design and a neat edge. In the Semco crochet books there are many dainty edges and it is very

interesting, if one is only a learner, picking out the edge. There are quite a number of stitches and one is never finished learning about needlework. For stems, use Satin and Stem and Snail-trail; for the flowers use Satin and Thousand-flower and Lazy-daisy. The Lazy-daisy is easy to do and pretty, too, but does not wear at all well; the centres can be done French-knots or Satin. Cross stitch is beautiful if done nicely and worked in colors. The back of the work must be as neat as the front and no knots, and if the work is for exhibition, always keep it in a pillow case to keep it clean.

JAMS.

[By Mrs. M. H. RICHTER, Wasleys.]

For making jam I prefer an enamelled steel preserving pan; a wooden spoon is advisable for stirring and accurate scales for weighing fruit and sugar. Do not wash the fruit, but wipe clean with a damp cloth. I never make jam in large quantities; small boilings are more satisfactory; 12lbs. at a time is enough, and only choice, firm fruit should be used.

Apricots should be a little under-ripe to make the jam a nice color, and figs quite ripe, as the jam will be juicier. Care must be taken to see that the berry fruits are not in a fermenting condition.

For most jams I add 1lb. of sugar to 1lb. of fruit, an exception being strawberry, for which I use 1½lbs. of sugar to 1lb. of fruit, and add tartaric acid. The acid counteracts the sweetness and the quantity of sugar increases the quantity of jam.

Some people put the sugar on the fruit overnight to extract the juices, but I prefer to put the fruit straight on the fire with a small quantity of water, about 1 cupful; cook until it pulps and then add the sugar and boil about 1 hour. If boiled too long, the flavor and consistency of the jam is spoiled.

For strawberry and raspberry 5 minutes is sufficient. Do not remove the scum that forms, it will disappear when the jam is taken from the fire. When making quince jam it is not necessary to peel the fruit. After thoroughly cleaning, place the quinces whole in the pan and cover with water and boil until soft, then cut open and remove the core. The remainder, and the water in which they were boiled, can then be mashed together and the sugar added.

Quite a number of fruits can be mixed successfully, for example, plum and blackberry, plum and mulberry, fig and grape, apple and blackberry, peach and pineapple, apricot and pineapple, also equal quantities of rhubarb and strawberries makes an economical jam.

There is no need for the jam cupboard to run low before the fruit season comes in as jam can be made from dried fruit. The recipe for dried apricot jam is:—2lbs. of apricots, 7 pints of water, 6lbs. of sugar. Wash the apricots and soak in water overnight. In the morning boil 30 minutes, add the sugar, and boil quickly for another 30 minutes.

Jam should be bottled while hot in small jars for preference. If glass, warm them in the oven to prevent cracking. Starch can be used to paste them down; label and date before putting away.

VEGETABLE DYEING.

[Mrs. M. C. DUNSTAN.]

Vegetable dyeing has a great attraction for most women. Besides the beautiful colors so obtained, there is always the chance of discovering fresh tints or rediscovering those which have been lost.

In the earlier days of dyeing, England produced most of her dyes from her own vegetation, but during the 17th and 18th centuries native dye plants were largely displaced by those imported. A few were still used, but they were finally ousted by chemical dyes in the 19th century.

The aim of vegetable dyeing is to obtain soft, rich coloring, and a greater permanence than can be obtained by chemical dyeing. The latter method can produce brighter dyes at a much less cost, but against this is the longer endurance of the vegetable dyes and their soft, lustrous coloring, by the side of which the chemical dyes are metallic and hard.

Also, the vegetable dyes, even when faded, retain great beauty and charm, as can be seen in old tapestries; they have lost their pristine brilliancy, but still retain their beautiful colors, whereas chemical dyes change, or even lose their color in the course of time.

Vegetable dyeing is much more expensive, and the method is far longer and more intricate than chemical dyeing, but the result is well worth it when applied to really good craft work. Persian carpets and rugs, which command very high prices, are all vegetable dyed, being made by a nomad tribe who live in tents wandering from place to place as the dye plants they seek are exhausted. There is a law, decreed by the King of Persia, that anyone introducing aniline dyes into the country will be punished with death; nevertheless, inferior aniline dyed rugs are on the market and can be detected by the expert. Vegetable dyes on the whole incline to soft shades, but many clear and brilliant colors are also obtainable.

Another factor which is against the commercial use of vegetable dyes is the unlikelihood of exactly repeating a color, so many factors, such as time of year, varying hardness of water, &c., influence the color. Also, personality plays quite a part, as two people can use the same yarn, water, and dye and yet produce two variant shades.

The vegetation of Australia offers an interesting field for experiment to the vegetable dyer, being mostly unexplored, and it may fall to the lot of the merest beginner to discover some useful and beautiful dye. The few people who are trying out our native flora have learnt in England, where also are written the few text books that we have, but the difference in climate, soil, &c., affects the dyeing qualities of a plant so much that the Australian value of an English dye plant has to be ascertained.

For instance, weld, a wild mignonette, is the best yellow in England; here, on trying it, the color produced was feeble and pale compared to our own quandong, gum tree tips, and many other wild shrubs. St. John's wort produces a yellow quite ideal for putting in the blue vat for green.

The predominating colors of our native plants are yellow, fawn, and pinkish-fawn. From onions we get many shades of orange and yellow. The green husks of walnuts give a beautiful brown ranging from nigger down to the palest tints of fawn, whilst from the lichens found on the rocks in our hills we get a brighter brown ranging from almost titian red through many shades down to cream. Wattle bark commercially used for tanning can, with different treatments, give us a different brown again, as well as useful shades of fawn and grey. The iris root yields an attractive pinkish-fawn.

The buckthorn yields a vivid yellow from its berries. These berries are imported to London from Persia and there sold as "Persian berries." On looking up their name I found that they were the same as the hedges so much in use here around gardens of 40 or 50 years ago. I brought home some berries and planted them and have two plants which are identical with our *rhamnus*.

The most interesting of my results are the dyes obtainable from the *drosera* (sundew) or fly-catcher, so called owing to the curious propensity of its leaves. The tiny bulb at the base of these plants gives a strong dye in shades of fuschia and cyclamen. With different treatments I obtained a most interesting range of colors.

In Scotland lichens are still used by the peasants to dye the wool for their own spinning and knitting and they are also used for dyeing tweeds. The well-known Harris tweed smell is due to crottle, a dye-bearing lichen. This is also used in Sweden and Shetland. Other dyes are made from lichens by preparation in various ways.

Indigo, prepared from the *Indigopera tinctoria*, which grows in Asia, South America, and Egypt, gives us the best blue, though the dyeing process is more difficult than most dyes. It has quite taken the place of woad, which was cultivated in Lincolnshire as recently as the beginning of this century. Woad is supposed to be the "vitrum" of the early Britons.

Logwood gives a greyish-blue, which is not to be compared with indigo for brilliancy and permanency. Several dyes are always included amongst the vegetable dyes, which are produced from an insect parasite. Cochineal, found in Mexico and commercially used for coloring, gives many beautiful reds and scarlets, also kermes, the "scarlet grain" of the old dyes, which is still used in the south of Europe, but can seldom be procured elsewhere. Its vivid color can still be seen on tapestries 300 years old.

Vegetable dyes are of two classes, substantive dyes which dye without any mordant and adjective which require the use of a mordant to fix the dye on the wool fibres. Most dyes are adjective. The word "mordant" comes from the French "modre," to bite, as the mordant enables the dye to bite into the wool and this fixes it. The mordant plays an important part in dyeing; with the same plant many distinct shades are obtained with different mordants. The simplest mordant is alum, and experiments with wool mordanted with alum will show if there is any dye of any value, and further experiments can be made.

To prepare the wool, dissolve 4ozs. powdered alum and 1oz. cream or tartar in sufficient warm water to let 1lb. of wool open up freely and absorb alum evenly in an enamelled vessel; bring this slowly to the boil, boil for one hour, leave overnight, and then wring wool out tightly, put into calico bag; this can be used at once, but is best after two or three days, and can be kept for several weeks. The bag should be hung in a cool place, such as a cellar. When testing a plant or bulb, boil up specimen in water in an enamelled vessel, let cool, take out specimen, put in a dampened skein of the mordanted wool, and bring to the boil—when color shows. It does not hurt the wool to boil it if brought gradually to boiling point; sudden changes of temperature are harmful. Vegetable dyes are particularly suited to wool, though silk will take some of them well, absorbing more dye than wool.

Cotton and linen, being vegetable fibres, require different treatment and are much more difficult for the vegetable dyer; in some cases the trouble and many processes necessary rendering it quite impracticable to the weaver. Cotton has, however, a natural affinity for anything containing tannic acid, so that with wattle bark fawns and greys can be got easily and inexpensively.

In choosing vegetation for dyeing experiments, it is not the brightly colored plants and flowers as a rule that produce strong dyes, native bulbs, hard, woody shrubs, and various gums are good subjects, and the easy and plentiful supply is a matter to consider; also the date should be carefully noted.

PREPARATION AND CURING OF PORK.

HOW TO TREAT AND USE A MEDIUM-SIZE PIG.

[Mrs. E. CATFORD, Riverton.]

Practically the whole of the pig can be used and there is not much waste. It is always advisable to kill in the colder months of the year, as best results are obtained in the setting of the meat. For instance, the pig of medium size (about 150lbs. to

200 lbs. in weight) is killed and cleaned in the usual way and left to hang on the gallows for about 24 hours to set. A good chopper, saw, and a sharp knife are required, and the operations are quite simple.

1. Saw down the pig from tail to nose; put it on a table and cut up one-half at a time.

2. Pull out the flat pieces of lard from the ribs.

3. Saw off the trotters, hind ones just above the hocks, and front ones just above the knees.

4. Cut off hams, leaving the sides as long as possible from bacon.

5. Cut off shoulders close to the shoulder blade.

6. Cut off the head just behind the ears.

7. Shape hams and take out the bone to the socket and nick off the socket knob with a saw.

8. Bone the shoulder and leave it in one piece to cure as bacon, or cut up into pieces of meat to pickle or roast as preferred.

9. Cut out the rib bones from the bacon side and level off the fleshy pieces of meat. These pieces are used for sausages.

This completes cutting up one-half of the pig; treat the other half the same except for the head and smallgoods.

CURING THE MEAT.

There are two ways of curing the meat, to dry salt it and pack it away into suitable boxes or to make a brine.

Obtain a clean pickling cask and sprinkle a layer of salt in the bottom of it. Put into a pan 6 lbs. of coarse salt and 6 lbs. of fine salt, 3 lbs. of brown sugar, and $\frac{1}{2}$ lb. of crushed saltpetre. Mix this well together and rub each piece of meat thoroughly with the mixture. Pack into the cask fleshy part upwards, and put bacon sides on top of the other meat. Cover over securely and keep in a cool place. Stand for about three days, then drain off the brine it has made and turn the meat about. Make another brine by filling a petrol bucket three parts full of cold water and dissolve into it as much salt as will float a fresh egg. Add the brine off the meat and bring all to a boil. Skim off the scum that may occur and stand overnight until cold. Next day pour it over the meat, which should be turned every day.

The pieces of meat will be ready for use in a few days. The bacon should be left in the brine for about a fortnight, and the hams about three weeks, according to size. Then take them out and rinse off the brine in cold water and let drain for a day or so.

TO ROLL THE BACON.

Beat out flat with a rolling pin and sprinkle a quantity of sugar, pepper, and spice over the meat side of the bacon; then roll up tightly, using a buckled strap to keep it in position. Put several coils of strong bacon cord around the roll about 1 $\frac{1}{2}$ in. between each strand, and make half-hitches to keep the cord from slipping, and tie securely. Sprinkle the hams with pepper and rub over the bacon rolls and hams with olive oil to keep the rind soft. Hang them up in calico bags to keep clean and they are ready for use at any time. Bacon and hams may be smoked if desired, or a quicker process may be made by adding a few drops of smoke essence when being cooked.

SMALLGOODS.

Take the head of the pig and cut off the cheeks and the tongue; rub these with salt and put them into the pickle. Then chop the head bones into about six pieces, after taking out the eyes and chopping off the nose. Put these into a dish of salt and water, leave stand for a day or two, changing the water each day. Then make brawn by putting it into a saucepan with clean water, seasoned with pepper, salt, and thyme, boil until all the meat leaves the bones, remove the bones, and put the brawn into a basin to set. When cold it will be quite firm to cut. The brains may be used if wished; they are very nourishing for invalids. The trotters are usually put into the pickle, but may be added to the brawn if preferred.

Clean the sausage skins and the "may" thoroughly and put them into salt and water for about three days, changing the water each day. Mince up all the scraps of meat that have been cut off when shaping the hams and bacon, add the kidneys and heart (if desired and if not used otherwise), also a quantity of soaked bread, some boiled pearl barley, and season with salt, pepper, and thyme; mix all this well together, and fill the sausage skins, divide into lengths, and boil gently for about 10 minutes; take them out and serve hot or cold. The "may" can be filled with mince meat and sewn up and boiled for a longer time, or boiled with the spare sausage skins, then sliced up and fried.

The sweetmeat makes a very delicious dish for those who wish to use it. This is usually fried. Boil the liver and when cold put through a mincer, add sugar, currants, and nutmeg to flavor. This mixture is very nice if baked in pastry. The lard must be rendered and put into a jar to set, cover over, and keep in a cool place. The pieces that are left after rendering of the lard may be added to the sausage meat, or, with other ingredients, made into a cake which is usually called "eritney" cake by the Cornish folk, and it is very delicious.

If black puddings are to be made, the blood must be caught into a dish while it is warm and stirred until it is thick, then add clean wheat and seasoning and make in the usual way. All the rib bones may be roasted or used up in many ways.

PRESERVING AND BOTTLING FRUIT FOR HOME USE.

[Paper read by Mrs. H. N. Wicks at the February meeting of the Balhamnah branch.]

Every home should contain as large a supply of different varieties of bottled fruit as possible, for what is more tempting during the summer months than cold preserved fruits ready for use from the pantry shelf?

There are various methods of preserving, the two simplest being on the vacuum principle, such as the Fowler method, or the open pan system. Those who have not a Fowler outfit can do quite well with a preserving pan, or the ordinary washing copper, a kerosene tin cut lengthways, or any vessel that is large and deep enough for the purpose. Place in the bottom a piece of wire gauze or a few slats of thin, narrow wood nailed together, or anything suitable to enable the water to circulate underneath the jars. Prepare the fruit which should be of that quality which could be classed first grade. It should be of good color, with a firmness of flesh and free from blemishes. It should not be over-ripe, because it requires to be sufficiently firm to stand the application of heat to which it is subjected, and still retain the natural shape. Wipe the fruit free from dust and pack regularly and neatly into the containers. The syrup may be of any desired strength and may be varied according to taste for most fruits. There are exceptions, such as strawberries and figs, when a heavier syrup is required. A syrup suitable and the one mostly used is made by adding 2 cups of boiling water to 1 cup of sugar. Strain through a piece of muslin and pour over the fruit, making sure the bottles are quite full. If using the Mason jars, place on the rubbers, screw the lids on *lightly*, or the jars may burst, place them in the pan, fill with water three parts of the way up the bottle and boil gently until the fruit is cooked.

Apricots, peaches, and soft-fleshed fruits require about half an hour. Cherries, quinces, and harder fruits need much longer. When cooked remove from the pan, screw lids down tightly, and keep out of any draught until cold. As the temperature of the contents of the jars gradually reduces there should be a strong suction, caused by the contraction and cooling off of the contents, and if any leakages are observed—these will be indicated by air bubbles entering the jar around the lid or rubber band—the cover must be released and the defect remedied. Store in a cool, dark place if possible, to protect the bright color of fruits, as they fade if constantly exposed to a bright light.

THE OPEN PAN SYSTEM.

This is another successful way in which fruit may be preserved, and is a very simple process. Make the syrup, and put into a preserving pan, prepare only as much fruit as will be covered nicely with the syrup, then bring gradually to boiling point and gently cook. Care must be taken not to boil too rapidly, or the fruit will become broken and loose in appearance. The time required will depend upon the variety of fruit under treatment, but until cooked through is sufficient. Have the containers ready and the rubber rings in place so that the boiling fruit can be bottled the moment it is cooked. Warm the glass jars before they are filled to prevent breakage. When ready place the bottle on a damp towel, gently fill the jars with the boiling fruit and syrup, then firmly and quickly screw on the lids, making sure that the jars are airtight.

When preserving pears and quinces, they should be bottled as quickly as possible after peeling, for they discolor and turn a dirty brown when exposed to the air. It is advisable to have a bowl of slightly salted water and drop the fruit into it until it can be placed in the bottles, and then cover quickly with the syrup. A little lemon juice or citric acid added to the water will also keep the fruit from becoming discolored.

Pack all fruits firmly and tightly without bruising, and grade the fruit an even size for appearance. There is a tendency for fruit to shrink in the sterilization and rise in the bottles, especially soft fruits; if packed firmly the appearance is improved. A heavy or strong syrup will cause the fruit to rise, leaving a space of clear syrup below. This does not matter for household use, but is unsightly when intended for exhibition purposes. Apricots and plums are very sensitive to heat, and if the fruit is fully ripened it is sure to rise a little in the bottles, and sometimes pushes out some of the liquid from the neck of the bottle, leaving the top piece uncovered. This is no detriment to the fruit. Large plums if cut in halves, pack more evenly and have a better appearance. The stone may be left in the fruit if preferred. If this is done a definite flavor is imparted to which some people are partial. Some varieties of plums, and also gooseberries, after sterilization, appear to be covered with small air bubbles. These are not air bubbles, however, and are caused through oil being drawn from the stones and skins, and will soon disappear after being stored for a while. This being the time and a good district for blackberries, those who are interested in bottling fruit should not miss them. Alone or mixed with apples they are delicious for pies later in the season.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

Dairying, at Milang, Wednesday, May 9th, L. E. Yelland (Secretary).

River Murray, at Barmera, Friday, June 22nd, C. W. Till (Secretary).

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th, A. R. Maguire, Mudamuckla (Secretary).

Upper North, at Wilmington, Wednesday, July 18th, Chas. Cole (Secretary).

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Retirement of Mr. W. L. Summers.

The recent retirement of Mr. W. L. Summers from the Public Service has meant an official break in our association with an officer who over a long period of time so ably conducted the affairs of the Agricultural Bureau and the *Journal of Agriculture*. Convinced that the Agricultural Bureau possessed great advantages to farmers and that it had a powerful influence on the development of agriculture in this State, Mr.

Mr. W. L. Summers recently retired from the office of Secretary to the Minister of Agriculture.

Summers learnt to regard the organisation more as a personal than as an official charge, and it can be said that even after he relinquished direct control the Bureau had not many more earnest supporters than he.

The Department of Agriculture may be assumed to have had its beginning in the Crown Lands Department as far back as 1887, and it was in that Department, as a junior officer, that Mr. Summers first became acquainted with the Agricultural Bureau which

was established in 1888. In 1892 he was appointed assistant to the then General Secretary and founder of the system, the late Mr. Albert Molineux. Later, in 1898, the duties of Chief Inspector of Fertilisers were added to his work, and in this he pioneered the administration of important legislation which has been a safeguard of users of fertilisers for many years.

In 1908 Mr. Summers was appointed Secretary to the Advisory Board of Agriculture, the controlling body of the Agricultural Bureau, an office which he vacated in 1910 to become the first Secretary to the Minister of Agriculture. As Secretary to the Minister he was made a member of the Grain and Fodder Board in 1914 and also held membership on the Fruit Board, Loans to Producers Board, and subsequently was appointed on the State Bank Board.

For many years Mr. Summers was a familiar figure at Bureau Conferences. He contributed several articles to the *Journal* and laid the foundation of experimental work undertaken by farmers throughout the State.

Argentine Wheat Position.

The Department of Commerce has received from Mr. W. J. Jackman, of Buenos Aires, a report on the Argentine grain trade for December last, in which official figures are quoted showing a total prospective export of 4,571,294 tons of wheat for 1934.

Commenting on the market position, Mr. Jackman states that very little can be said with regard to market operations at the present time, as these are almost completely in the hands of the official Grain Control Board which was established by the Government in the closing days of the month of November. The Control Board was created in order to put into effect a plan devised by the Government for extending assistance to the wheatgrowers of the Republic. Briefly, the plan is that the Grain Control Board will from time to time establish basic prices for the produce dealt with (wheat, linseed, and maize), and will purchase at those basic prices all such produce as may be offered to it, afterwards reselling it, for export only, in accordance with the prices prevailing on the world's markets. Another official board, the Exchange Control Commission, daily establishes the rate at which the banks shall purchase the exporters' bills. The exchange thus made available is sold daily to the highest bidders, and any resulting difference is credited to a fund from which the Grain Control Board will meet such losses as may be incurred in its grain operations and also the expenses of the board. According to Ministerial declarations, it is not the intention of the Administration to use any public funds in support of the scheme beyond those obtained in the manner indicated. Nor is it the intention to make the arrangement a permanent one. It is merely a temporary plan for ensuring that the aid intended for the agriculturist shall actually reach him, and not be absorbed by the intermediaries by whom his grain is ordinarily handled.

The grain is accepted by the board at whatever railway station or port is convenient to the producer, and it is held in store at that point until resold to the exporters. Eighty per cent. of the purchase price is advanced to the seller by the local branch of the National Bank upon delivery, and the balance is paid upon re-sale being made to the exporters, after the establishment of weight and grade by the customary methods.

As will be readily understood, the establishment of this system has involved a very radical change in market conditions, and the result is that the futures market is almost stagnant, the number of transactions taking place on the floor being very small indeed. Country grain dealers are still able to do a certain amount of business in competition with the Control Board, by paying cash in full for their purchases, as many owners of grain are willing to sell at a slightly lower price on those terms, rather than wait an indefinite time for the balance of 20 per cent. necessarily held back by the official board pending resale of the grain. Some speculative purchases are also being made at the full official price, on the theory that if the markets outside advance a profit may be made, whereas if they fall the grain can still be sold to the Government at the guaranteed price and only a small loss involved.

VACUUM OIL COY. PTY. LTD.

Naturally the operations of the official board are kept secret, and no information as to its transactions is given out. It is, however, known that there has been some direct selling by the board to the English Co-operatives, the amount of wheat involved not being announced, although gossip sets it at ten cargoes.

Brazil continues to be the principal buyer of Argentine wheat, and the pick of the grain of the new crop coming forward at northern points is being purchased for the Brazilian millers.

Wheat Flour.—An interesting development during the month has been the publication of a decree prohibiting the exportation of flour containing any form of chemical improvers, followed a few days later by the prohibition of the sale of such flour within the Republic. As practically all flour milled here contains improvers, some little consternation has been caused amongst the millers.

It is believed that the initial action was taken at the instance of the Brazilian authorities (Brazil being the principal export market for Argentine flour), no doubt prompted by the Brazilian millers. And the Argentine Government's willingness to comply with the Brazilian representations, and even to go a step further, was probably due to a desire to raise the level of the quality of the wheats produced here, so that no artificial improvers may be necessary to secure the desired color and strength.

A similar ambition has led the new Wheat Control Board to outlaw certain varieties of low-grade but high-yielding wheats from the higher classifications of export wheats, and so help to pave the way for the official grading system to be established when the new Grain Act becomes law and when there is an elevator system to make its operation possible.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

Tantanoola Conference—"What is the best method of destroying bot fly eggs on Horses?"

Reply—Clipping the hair closely off parts liable to be struck helps to prevent the deposition of the eggs. 2. Singeing the hair of the area over which the eggs are spread will help to destroy them. A taper or candle could be used. 3. The application of the following dressing, twice daily, is useful to prevent strike:—Creosote, 1 part; oil of turpentine, 6 parts; raw linseed oil, 20 parts.

Tantanoola Conference—"What is the cause of blindness in sheep at this time of the year?"

Reply—Where a number of sheep are affected, the disease is probably "Pink-eye" (contagious ophthalmia of sheep). It is due to infection by a germ and spreads very rapidly through a flock. It is common in travelling sheep, and is usually introduced into a farm with bought sheep. There is rapid loss of condition and feeding becomes difficult. The eyes are very painful and may rupture. Treatment consists in isolating all affected sheep and making provision for good feeding, ample water supply, and shade for them. Further, put a few drops of a 5 per cent. solution of zinc sulphate in the affected eyes daily for a few days.

Tampanoolia Conference—"What steps should be taken to prevent red worms in water troughs?"

Reply—The red worms seen in water troughs are not dangerous to farm stock. They are the larvæ forms of an insect and not, as many think, the "blood worms" which affect horses.

"Huddleston" asks what are the reasons for a cow not breeding. Reply—These may be:—(1) The bull may be at fault. This is not probable and can easily be proved or otherwise, *e.g.*, by change of bull or failure of bull to get any cow in calf. (2) The cow may be at fault. This is the usual reason. The causes are many, and are:—(a) *Nutritional Reasons*.—The cow is too fat, or a debilitated condition may be the cause. The part nutrition plays can be shown by good results following "flushing" of ewes. (b) Disease of the ovaries. (c) Chronic inflammation of the breeding-bag following retained membrane and abortion. (d) Catarrh of the outer passage. A change of bulls is recommended, and preferably a young one which can be allowed to run with the cow. Other treatment which gives good results is to douche out passage twice weekly with Condy's crystals solution (port wine color), used at blood heat. Stop one week before heat comes on and one hour before service rake out and douche with bicarbonate of soda solution (dessertspoonful to a pint) used at blood heat.

"Clarendon" has mare lame in both fore feet, which are puffed, hard, and very tender. Difficulty in walking down hill. Reply—From the symptoms and history supplied, the lameness is probably due to deformed feet, the result of an attack of laminitis (founder). Try the following treatment:—Twice a day for a week give two tablespoons of baking soda in feed and if possible reduce grain. Have the horse shod with a shoe thick at the quarters and tapering off towards the heel and toe, which in effect is a "rocker" shoe. If the soles of feet have "dropped," it will be necessary to have a wide webbed shoe fitted so that it extends over the sole a little way, but "seated" in order that shoe does not exert any pressure on the sole. Animals which have been foundered can be used for breeding purposes.

The AVERY Rabbit Exterminator

PATENTS PENDING—Numbers 4387-31. 6867-32.)

Is a light, self-contained outfit which forces dense volumes of smoke and poisonous carbonaceous gases into the warren. The operation of the "AVERY" Exterminator is simple, safe, and inexpensive, as the poisonous gases are scientifically produced by using only damp straw or grass, etc., supplies of which are available on every farm and station.

POSITION OF AUSTRALIAN WHEAT INDUSTRY.

(Statement for the Wheat Growers submitted in evidence by Mr. C. A. S. Hawker, M.H.R., to the Royal Commission on the Wheat Industry.)

SIZE OF INDUSTRY.

The Wheat Industry is the largest contributor to employment in the Commonwealth. It is the greatest of all primary industries in the bulk of its output and second only to wool in the value of its production.

For the very reasons which make wheat farming the great work provider of the Commonwealth, it is very hard for the industry to extricate itself from the present crisis. The fact that so much work is provided on railways, at the seaboard, and in the factories means that much expenditure must be incurred by the farmers for transport material or machinery. The wheatgrower so long as he continues to grow wheat cannot escape the costs of these services nor under Australian conditions regulate their rates. To the extent that he ceases to grow wheat in favor of a more economical crop he escapes from a proportion of the expense and the people whose work provides the services lose their living.

You, Mr. Chairman, have estimated that about a million people in Australia are dependent directly or indirectly for their means of living upon the wheat industry.

In 1931-32 wheat bounty was paid to 74,816 individual growers who produced wheat for sale, and the Commerce Department considers that approximately 65,000 of these grow wheat as the main source of their livelihood. In addition to this large number of individual farmers there are many tens of thousands of farm laborers and casual laborers who obtain employment at harvest or seeding.

The wheat belt is the main area of comparatively close settlement inside the Dividing Ranges of Australia. Throughout the wheat belt the populations of townships are dependent for their business and existence upon the wheat industry.

IMPORTANCE TO RAILWAYS AND HARBORS.

The wheat industry is the largest contributor of freight to the railways. During recent years the tonnage of wheat carried has approached 4,500,000 tons per year. In the State of Victoria alone it has averaged well over one million tons during the last three years, contributing three-quarters of a million pounds in revenue. This represents about 20 per cent. of the total tonnage carried and rather less than 20 per cent. of the total goods revenue. A great deal of back-loading and other freight is also provided by the wheat industry.

In States more dependent upon wheat growing the financial position of the railways and the employment of the railways staff are even more wrapped up with the position of the wheat industry.

The Harbors are also vitally affected by the wheat position. Approximately three and three-quarter million tons of freight have been contributed by the export of wheat during the last three seasons. This has not only meant work on the waterfront, but port and harbor dues to the great public authorities which control the harbors. It also means business for ships' provisions and supplies.

Three-eighths of the net tonnage of all the shipping cleared with cargo from Australian ports during the last three years has been required to lift the wheat crop alone (See Table "A.")

TABLE A.—*Exports of Wheat and Flour from Australia.*
(December 1st to November 30th.)

GROWTH OF INDUSTRY.

Since the use of superphosphate became general during the early years of this century the expansion of wheat farming has been rapid, and except for a setback in the later war and early post-war period, continuous. Before the days of superphosphate wheat farming had only been successful in districts of relatively good rainfall. Subsequently the wheat belt extended inland. New wheats and better dry farming methods consolidated the new areas. Even in Northern New South Wales where fertiliser is not required, wheatgrowing seemed to have expanded simultaneously with the adoption of better farm methods evolved to suit those districts further south where wheat growing had been a failure without superphosphate. The Table marked "B" gives an outline of the statistics showing the acreage, the yield of wheat in five yearly rests since 1911, and such figures as are available for recent years. It also shows the relation which the area cropped for wheat bears to the total area under crop and the value of wheat compared to that of primary and agricultural production. Comparative figures for exports values are also included. It will be seen that for the three years of which 1911-12 was the middle year, the average crop was 86.24 million bushels, with an average of 11.69 bushels per acre. During the last three years for which statistics are available, of which 1931-32 is the middle year, the total crop averaged 205.5 million bushels, and in spite of the large increase in the area cultivated and its extension inland to drier districts, the yield per acre had increased to 12.83 bushels. This shows not only an enormous increase in the crop, but a definite improvement in returns per acre. When the considerable area which is still only partially cleared and improved is taken into account, the soundness of the main development becomes obvious. No doubt there is a ragged fringe of inferior country which trial has now demonstrated to be unsuitable for wheat growing, but this must not be confused with districts from which low returns are inevitable during the developmental stage. Many localities which are now recognised as well established farming districts had a record of dismal failures during their period of development.

PLACE AMONG RURAL INDUSTRIES.

Table "B" also shows the stability of wheat as the main agricultural crop. The ratio of land under wheat to that under all crops has increased somewhat since 1911, although the percentage has not greatly altered. In 1911 it was 61.3 per cent. out of a total of 12.1 million acres, while 1930-31 it rose to the peak of 18.16 million acres out of a total of 25.16 million acres, or 72.19 per cent. In that year the areas were affected by the "grow more wheat" appeal of the Federal and State Governments. The routine of farming was disturbed, but nevertheless in spite of the fall in wheat acreage to 14.7 million acres in the following year, that was still 69.6 per cent. of the total area under all crops.

The pre-eminent position of wheat farming as an alternative to grazing in districts of medium rainfall has made wheat farming the basis of much closer settlement. This probably accounts for part of the increased proportion of the wheat area and the rest is due to the opening up of large scrub areas in the Mallee districts of the Eastern States and in the scrub belts of West Australia. It is only after long established settlement has been achieved and extensive improvements provided that such districts can diversify their farming profitably.

DIFFICULTIES.

To-day the position is in serious jeopardy. The depression has affected all sections of the Australian people, but none have felt it more severely than the wheat growers.

The price of wheat at the sidings has fallen to little more than two-thirds of pre-war price. Whereas the cost of production has fallen comparatively little from the level which it reached during times of post-war prosperity that was enjoyed by all sections of the people of the Commonwealth.

In 1911-12 the crop of 71.64 million bushels was worth £13,300,000. In 1926-27 the crop of 160 million bushels was worth £42,450,000. (See Table "B"), and all Australian standards were raised in conformity with the prosperity of the Man on the Land. In 1930-31 the record crop of 213.59 million bushels was worth only £25,000,000. Had it not been for the large quantity, the position would have been much worse. This year the price is almost as low and the total crop is about one-quarter less. These estimates are for values at the seaboard end, when allowance is made for the very slight reduction in handling costs and rail freights, it will be plain that the actual shrinkage of farmers' incomes is correspondingly more severe. The particulars of Returns to farmers who were members of the Victorian Wheat Pool show this plainly.

For a limited time a considerable part of the industry was able to carry on by using up reserves, but the position has become steadily worse. The wheat prices which reached their lowest point for all time in 1931 rallied slightly in 1932, but receded again last year, and now are falling to what threatens to be an even lower record than that of 1931.

TABLE D.

The distribution of the proceeds of the crops and the payments to farmers' creditors resulted approximately as under:—

	Farmers' 1931 Season. Per Cent.	Farmers' 1932 Season. Per Cent.
Paid all creditors	4.4	1.5
Paid interest, rent, &c., and dividend on antecedent debt ...	30.2	9.2
Paid advances and dividend to interest, rent, &c.	39.7	34.1
Partial failures	20.6	49.8
Total failures	5.1	5.4
	100.0	100.0
Farmers approved	3,459	2,698

These percentages are taken on the total number of applicants approved for relief.

EVIDENCE OF REGRESSION.

It is natural that the breaking point should be reached first at the weakest points in the industry. That is, in the pioneering districts. The West Australian wheat belt is the most recently opened up, and therefore in much the weakest condition to withstand a period of stress. The partly cleared paddocks cannot be let stand. Money must be spent to safeguard the ground that has been partly won. There is not the same opportunity for the pioneer to cut down his expense which presents itself to the established farmer. In West Australia over a thousand farms are reported to have actually been thrown back on the hands of the agricultural bank or other creditors, and a very large proportion of the others are being worked under various forms of supervision. In the other States a similar loss of ground has been occurring. Farmers are protected from bankruptcy proceedings or foreclosure by moratoria or the protection of debt adjustment boards. Many of them are also receiving assistance and protection from various State Authorities, particulars of which will be submitted to the Commission in the evidence. In all districts there is to be seen dilapidation of improvements, depreciation of plant, a spread of noxious weeds, which are signs of a losing battle. This year the rise in wool prices has brought fresh hope to the mixed farmers, but where the holdings are too small or the water and fencing inadequate for live stock to be carried there is alarm and sometimes despair.

The rate at which many farmers have been losing ground can be estimated by the figures which have been published concerning some thousands of wheat farmers in South Australia who have been working under the supervision of the State Bank. These are no doubt farmers on worse than average country, but on the other hand it is almost certain that they have less than average total liabilities. During the 1931-32 season 34.6 per cent. of these farmers paid their expenses, their commitments for interest, and something over to reduce their liabilities; 39.7 per cent. paid their working expenses and something towards the interest on their capital commitments; and 25.7 per cent. actually failed to produce wheat for sale of sufficient value to cover the new money which they received for working expenses.

The following season, 1932-33, the position was very much worse: only 10.7 per cent. made any headway; 34.1 per cent. covered their working expenses and a little towards interest on their liability; while 55.2 per cent. failed to receive returns which covered the assistance they had received for working expenses. Both of these years were seasons that were well above the average. For the

current year the season is not so good and the price of wheat definitely lower. The results will certainly be even more discouraging. This can be taken as fairly typical of the position of farmers who are in comparatively new districts. (See Table "D.")

DEBT STRUCTURE.

On better land the yields are higher and the returns more generally cover actual working expenses, but in most of the better districts the cost of working the land is definitely greater and, in the majority of cases, the interest charges are heavier.

The years after the war were a time of inflation in all business. Instalment purchase was a growing feature. Banks added their tacit sanction to the general trend by many advances for the purchase of land. Values of produce and of land were translated into units of the paper currency of the time. The depression developed rapidly everywhere, but its blast struck the primary industries with unparalleled suddenness. Within a few months the price of wheat plunged from a comparatively high level to depths lower than it had reached during centuries. History has recorded no example from which a warning of the possibility of such a disaster might have been learnt and provided against.

Before the depression a revolution in farm methods was also leading the wheat growers into unusual capital expenditure. Newer and larger machinery was being invented which made production cheaper and easier provided the area farmed was large enough to carry the overhead expense of the new up-to-date plant. The big implements were made easy to acquire by hire purchase; kerosene was available on astonishing terms, but additional land to keep the farmer and his fine plant fully occupied was not readily available. When land did come on the market it was hungrily bid for and more liability incurred by farmers who purchased it, often with aid and approval of banks.

The wheat growers as an industry were therefore caught in a transitional stage with more than their average of liability by the depression which struck them with more than average suddenness and severity.

Some estimate of both the size of the industry and the serious position in which it finds itself can be made from a computation of the aggregate liability of farmers. In both South Australia and West Australia fairly thorough inquiries have been made during the last two years. In West Australia a Royal Commission reported that the aggregate of certain classes only of liabilities of farmers (but including some mixed farmers) were more than £31,600,000.

In April of last year the Royal Commission in South Australia which investigated the matter estimated that the liabilities of farmers in that State aggregated about £38,800,000. This is almost certainly a fair average of the liabilities of farmers in all wheat-growing States, and on this basis, even with some deduction for debts of grazing farms, a conservative estimate of the aggregate liability would place it at well above £150,000,000.

This huge figure represents the debts of farmers, but at the same time these debts are among the assets of the Australian business community. No doubt some of them are not well secured, but it is obviously to the interests of all sections of the community that every reasonable step should be taken to protect the solvent part of this asset from unnecessary deterioration. These debts and their security have become part of the financial structure of the Commonwealth, and it is in the interests of the general public as well as those of the farmers to ensure that the structure is not undermined by any avoidable disintegration in the industry which forms their security.

DISCOURAGING PRICE OUTLOOK.

During the closing years of the last century when the wheat industry was also faced with very low prices, the suddenness of their fall was less severe and the length of time during which low prices ruled was much briefer than on this occasion. At that time farmers were also free from a number of handicaps which seriously impede them at the present time. The Australian level of taxation was low and the prices of the things which the farmer found it necessary to buy also fell. It was therefore possible to carry on with wheat prices round about 2s. or less per bushel, where to-day such prices spell ruin. There was also a better prospect of the prices of wheat improving. To-day there is a number of adverse factors which make the outlook very dark indeed. Details will be communicated to the Commission by expert witnesses; but broadly outlined, a large sections of the nations of the world, previously importers of wheat, have closed their markets against imports for economic and national reasons. This has restricted the field of the wheat trade very drastically, and the best information appears to offer little hope of re-opening of these markets. International trade is tending to become more and more a matter of barter hedged within the terms of reciprocal quota agreements between individual countries. When Australia's tariff hostility to goods of other countries is considered, our farm exports appear to have less chance of regaining their foreign markets than of losing still more. As well as these obstructions to the trade in wheat, the outlook to-day is darkened by the existence of huge stocks of carry-over wheat which were built up during the years immediately preceding and at the commencement of the depression. These stocks are mainly held in North America, and, in spite of short crops during the last two years, in both Canada and the United States, the carry-over has tended to increase rather than to diminish. It appears that the existing world demand for wheat is not large enough to reduce the carry-over as well as absorb the current production at a payable price. Economic and seasonal influences which will ultimately raise demand, or curtail supply, therefore may take a considerable time to correct the position.

The Commission no doubt will make a comparison between the position of the wheat market sunk down by these big accumulations of unmarketed wheat and the position of the wool market, buoyant because of its complete freedom from any carry-over. The notice of the Commission is drawn to the fact that this carry-over was not contributed to in any way by the farmers of Australia, and this fact illustrates the way in which Australian farmers are at the mercy of world conditions and reactions of farmers and Governments in other countries.

SUBSIDIES IN OTHER COUNTRIES.

The Commission may consider that the wheat industry would recover more rapidly if it was left, like the wool industry, to find its own level. This may be the case if the same rule were applied throughout the whole world, but in the face of the assistance to farmers which is being provided by Governments in other countries, any abandonment of the Australian wheat industry to its fate would lead to the elimination of a large area of entirely economic farms in Australia and leave the farmers of other countries to be the main beneficiaries of any improvement in price which followed the correction of supply to the world demand.

The extent to which other countries assist their farmers can be gauged from the following information supplied to Parliament in November.

Among the countries which formerly imported wheat several have imposed quotas on tariffs which have made wheat so profitable to their own farmers that they have now little need of imports.

In France farmers last year received the equivalent of 9s. 10d. in Australian currency per bushel, in Italy 11s. 5d., and in Germany 9s. 4d. In Great Britain the price of home-grown wheat is guaranteed at 5s. 7½d. a bushel, equal to 7s. 0½d. in Australian money. In New Zealand the price varied from 3s. 9d. to 4s. 1d. per bushel.

Among the exporting countries various steps were taken to increase the returns to wheat growers.

In Canada on the date in November in question the price was about equal to 3s. a bushel, and this was partly maintained by Government operations on the future market.

It is difficult to follow all the ramifications of policy in the United States. A Process tax (roughly the same in principal as the Australian flour tax) was imposed to raise funds in order to compensate farmers who would agree to seed a smaller acreage. It is uncertain whether some of its proceeds is not also applied for support of the wheat market, but the Chicago price has been above export parity for some time.

In the Argentine the Government has lately proclaimed a price at which it will buy all grain offering, and has set up an exchange board which pays any profit on exchange into the account of the Grain Board in order to make up any loss which the latter may incur in its transactions.

In the face of these circumstances it is plain that nothing but a considerable wastage in one of the Commonwealth's most valuable assets could follow from the abandonment of the Australian wheat industry to an unequal life and death struggle with competitors who are receiving such aids.

HIGH COSTS OF MATERIAL.

The fact that costs of production remain very high in Australia and that this has been partly caused through the effects of the Australian tariff policy is another reason why Australian farmers should in justice be assisted to struggle through against the competition of highly subsidised wheat from other countries.

The accompanying Tables ("E") prepared by the Director of Agriculture in South Australia, show that essential material, some of it imported free of duty, purchased by farmers which in 1913 would have cost £91 13s., and in 1925 £129 9s. 6d., would this year cost £100 13s. 1d. Although there is a welcome reduction since 1925, the aggregate price of this material still is 9.8 per cent. above the price of 1913.

Essential miscellaneous tools (not all of which are protected by the tariff) show an even greater rise. In 1913 an assortment of those essential on a farm could have been bought for £3 9s. 3d.; in 1925 the cost had more than doubled at £8 15s. 2d. This year the price has come back substantially to £5 17s. 5d., but this is still more than 40 per cent. above the 1913 price. In the matter of harness, the prices this year average more than 41 per cent. above those of 1913, and essential farming machinery 31.7 per cent. (The latter figure has since been corrected to 36.69 per cent.)

The comparison for farming machinery is more difficult to make, because of the change in types, but the cost of plant upon the farm can be safely stated as still considerably above 1913 prices; while the price of produce is disastrously below those prices.

In 1928 enough superphosphate to apply 90lbs. an acre over 100 acres could have been purchased for the proceeds of 76 bushels of wheat. This year in spite of some reduction in the price of super it would require the proceeds of 180 bushels. In 1928 the South Australian railways carried 100 bags of wheat for 150 miles for freight equal to the value of 25 bushels. This year even with some reduction in freight rates the cost to the farmer equals the value of 62½ bushels. This is typical of the position in regard to the relative cost of material and services in all States.

Under these circumstances, the Commission will readily appreciate the justice as well as urgent need of assistance before more farmers sink into insolvency, more plant and improvements deteriorate for want of upkeep, before more land is reduced in fertility because of catch farming by farmers in their honest endeavor to grow enough to meet their commitments.

WORLD WHEAT SCHEMES.

The Commission will have the duty of ascertaining the best means by which the Federal Government can give assistance and the measure of such assistance. Doubtless, they will examine what may be expected through International action to assist the wheat industry on a world basis.

It appears that the existing International wheat agreement has had neither good nor ill effects. It was hoped in some quarters that it would afford such a relief of pressure upon the market by sellers as would raise prices to a point where importing countries might reduce their restrictions upon trade. This has not been the case up to the present. The price of wheat has, in fact, fallen steadily. The Commission can no doubt usefully inquire as to whether the agreement has in effect prevented a more drastic fall in prices than that which has actually occurred.

Possible International action might be attempted along several lines. The actual movement of wheat might be further limited in a way similar to that provided by the existing International agreement, or the shipment of wheat might be made conditional upon sale at a minimum price. Hitherto Australia has at least escaped the embarrassment of holding any large carry-over of surplus wheat. Unless any further world agreement contains sure safeguards for cutting the world's aggregate surplus, it appears to be dangerous for Australia by joining it to limit her export in such a way that the net result might be simply to transfer a surplus from North America to Australia. Any scheme which raised the price without diminishing production would be in danger of breakdown under a growing carry-over. Actually a better price might induce greater production.

It is suggested that, if the limiting of the right of export alone would not be effective because it would not have a deterrent effect upon sowing by farmers, that the compulsory holding of wheat in excess of a certain quota of wheat upon the farms would certainly lead to curtailed sowings. In other quarters a compulsory reduction of the acreage seeded has been advocated as a means of reducing the surplus of wheat to an amount which can be sold at a reasonable price.

As a grower representative of growers' organisations, I feel qualified to advise the Commission that the difficulty of policing of such schemes and their inequity as between individuals, appears to render them quite impracticable.

An intermediate scheme by which farmers were compensated by the United States Government for reducing their acreage is reported in press cables to have broken down owing to the increase of seeding by farmers in what are not normally regarded as wheat producing districts. Such cables may not give a fair account of the actual facts.

In West Australia a suggestion has been made that aid in the form of bounty on home price should be confined to farmers who agreed to reduce their acreage. A thorough report on the working of the somewhat similar scheme in the United States should therefore be obtained and carefully examined. With the present disparity between the price of wheat and that of some other primary products there is little doubt that wherever circumstances of farm management and of finance permit there will be a natural swing away from wheat cropping. In Australia, with the present prices for wool, this will be especially strong. But

it is difficult to estimate how much relief will result to the wheat market. In any case a natural change over is preferable to one which is enforced by Governments.

NEED FOR LOWER COSTS.

The Commission should examine the possibility of the gap between the costs of production and market price being reduced by lower costs. There is no doubt that the farmers have stinted and sweated themselves to a remarkable degree in order that their costs might be lowered and in order to do their best in both their own interests and those of their creditors. The Commission will find ample evidence of this in the accounts of the large number of farmers who are working under supervision by Farm Relief Boards or other authorities established to assist them. The accounts of these farmers, however, disclose that there is still a substantial gap between the annual commitments, even on this sweated basis, and the price which the farmer is receiving for his produce.

INTEREST.

There is a number of farmers' costs which are beyond control. Probably to-day interest on the huge debt is the heaviest. The rehabilitation of the farming industry is probably more dependent upon a cheap money policy in Australia than upon any other single factor except the world price of wheat.

The Premiers' Plan cut in interest was a great help. Since then the representatives of Australia at the London Economic Conference last year were parties to the agreement of British Empire countries to follow a cheap money policy, and the tendency of interest rates has been downward. There is, however, a feeling among farmers that the results of that policy are not developing with enough promptness to prevent a ruinous accumulation of interest arrears.

When farmers are losing ground financially they cannot be expected to appreciate the benefits of keeping Governments from interference between debtors and creditors. The fact that the fear of renewals of such intervention have the effect of diverting fresh investment away from mortgage on land and thereby reducing the chances of borrowing at lower rates to pay off old liabilities, seems academic to those who can only see an interest bill which is destroying their chance of regaining solvency. Delay is therefore certain to strengthen pressure for another statutory cut such as that provided for under the Premiers' Plan. The factors making for delay, such as competition by the Savings Banks for deposits, founding of treasury bills, taxation, &c., might be lessened through a wider knowledge of their existence.

DEBT ADJUSTMENT.

In any case the Commonwealth by itself does not have the power to deal with questions between farmers and their creditors except through the processes of bankruptcy law. The States, however, have power to take steps which make possible the scrutiny and reconstruction of the position of many farmers. Where this is carried out with proper discrimination there are mutual benefits to both the farmer and his creditors.

There is a variety of statutes which deal with the question of adjustment of debts. There are also laws which give the protection of moratoria. The Commission will no doubt examine the working and effects of all these.

It is pointed out that, although on the whole the larger creditors, whose assets are considerably dependent upon the value of land which is the security for numerous loans, have shown forbearance and a helpful attitude, many smaller creditors have attempted to act in such a way that, apart from any harshness to farmers, their action would have precipitated forced sales to the danger of general value of land as any basis of security.

It is important that carefully considered laws made by the States to deal with the emergency should not be rendered invalid because of any conflict with the provisions of Commonwealth Bankruptcy Law.

Some portion of farmers' debts are not secured, or not fully covered by the present or the prospective value of security. In some cases it has been possible to arrange compositions by which creditors are glad to give a very substantial discount for ready cash. The extent to which the credit of the States or the Commonwealth might be used to raise money at low rates of interest to partially liquidate the Farmers' debts in this way should be examined.

TAXATION AND RAIL FREIGHTS.

A factor in high costs of production is high taxation. It is generally recognised that a cheap money policy is absolutely dependent upon the national budget being balanced, and, for that reason, severe taxation is difficult to avoid. It is also recognised that the Federal Government has done a considerable amount to exempt farm produce and farm requisites from Sales Tax and primage, and in some States the State Land Tax and Local Government Rates have been slightly lowered.

There are, however, still many items of taxation which directly handicap the farmers' operations. For instance, a very heavy revenue duty is levied on petrol, and portion of it is allocated for road maintenance and development. The exaction of this tax from farmers who use petrol in stationary engines or in farm machinery or in tractors, is a direct impost upon his means of production. Even where it is possible to run a tractor actually designed to consume petrol, with kerosene for its fuel, there is some loss of efficiency and increase in wear and tear. Sales Tax is still levied on kerosene, lubricating oil, and grease.

The special Federal Property Tax upon income derived from interest on mortgage is, even at its reduced rate, still an appreciable factor in keeping up the rate of interest. The Federal Land Tax falls upon only a minority of wheat farmers, but in places it is a check to the consolidation of inferior holdings which is undoubtedly desirable for the efficient working of the land in marginal districts.

In the primary producing States the wheat farmers are called upon to pay State Land Tax as well.

Rail freights have recently been slightly reduced from the post-war peak, but they also remain in all States at a very high level in comparison with those before the War. Harbor dues wherever charged upon wheat or farm requisites are also high.

EFFECTS OF TARIFF.

The Federal Tariff has a double effect upon the cost of farmers' operations. It raises the cost of a number of his essential requisites, such as some of those enumerated in the Table referred to above, and as such, is a tax which discriminates against him. It has, moreover, a more serious effect owing to the general increase which it causes in the cost of living, and, through the resulting increase in the cost of living index figure, its raising of the basic wage. These increases bring no benefit to the Australian wage earners, since they merely make good their greater expenses. On the other hand, the farmer who has got to sell his produce in markets outside Australia suffers by not being able to raise his returns in accordance with the rise in the basic wage and Australian costs.

The depletion of the farmer's income through these indirect causes is probably a greater burden from the general tariff than the actual increase in the prices of farm requisites due to the tariff upon those items. The combination of both imposts certainly adds several pence per bushel to his costs of production.

The tariff also has an effect upon the overseas freight which the farmer pays to market his wheat. The fact that trade has become so considerably a one-way traffic has meant that the shipping which comes to Australia nearly empty is forced to charge most of its expenses of the round voyage upon Australia's exports.

In certain localities there is an added disability of a similar nature. When the tariff was lower and many more finished articles were imported, there was a great deal more direct importing to all the chief distributing centres in Australia. To-day those imposts which continue are proportionately more in the nature of raw materials which come to the ports of Melbourne and Sydney for use in the great industrial centres adjacent to those ports. As a result shipping which caters for parcels of wheat finds intermediate ports such as those of South Australia less attractive and freight rates are correspondingly increased.

Resentment in some Overseas Countries has so grown at the unreasonable height of the Australian tariff that measures of retaliation have actually been taken in some cases and threatened in others. This has tended to deprive Australian wheat of the premium value which it once had for blending with other wheats.

At a time when Australian wheat-growers are struggling for their existence in competition with wheat-farmers in other countries who are free from such burdens it is simple justice that these disadvantages should be removed or made good in some other way.

EXCHANGE.

Closely allied to the monetary policy of Australia as it affects interest rates is the question of exchange. A high exchange rate is a substantial help to all the export industries to carry on. From time to time expectations arise among interested people that the exchange rate will be lowered. In certain quarters there is a belief that some special virtue would arise from the re-establishment of the Australian pound on a parity with sterling. From the point of view of production and employment in Australia there can be no doubt that any such lowering of the exchange rate would cause a severe setback, and not only would the adverse gap between costs and prices measured in the Australian currency be widened in the case of most of the export industries other than wool (at the present time), but the uncertainty caused by a moving exchange rate would make it necessary for traders to work on wider margins.

Some people have an impression that London funds may grow to such a large amount that the exchange might be broken downward by outside dealers in the same way as it was broken upwards in January, 1931. This is erroneous. There is no real similarity between the impotence of the Commonwealth Bank in 1931 to hold down the rate at a time when it was losing London funds and could not find sellers ready to let it have British money for Australian money at a lower price than the outside purchasers were prepared to pay and the unlimited power it always has to hold the market up so long as it is prepared to buy at its price. No one offering less than 125 would find a seller of exchange so long as the Bank was prepared to pay 125 for exchange. Long before any dangerous inflation occurred in Australia the Australian funds issued by the Bank for the purchase of London funds would necessarily start money circulating and stimulate employment. From that a demand would arise for London funds to pay for imports and relieve the Bank of some of its volume of such funds. If the bank decides to lower the exchange it can only be because by cold calculation the board has decided that employment and prosperity in Australia are excessive and should be checked or else that it is desirable to enhance the dignity of Australia by deflating the Australian pound to parity with sterling.

There is a general agreement among producers that, failing a managed currency which would give some stability in price levels, nothing but adverse results could arise from a lowering of the exchange rate merely for the vanity of re-establishing the Australian pound at parity with sterling.

PREVIOUS GRANTS.

Even with the reductions in costs that have taken place and the slight raising of the price of exports in the terms of Australian money as a result of the exchange, there remains a wide gap between costs and prices.

The Commonwealth has already contributed some assistance to lessen this. In three years approximately £8,400,000 has been distributed in the form of bounty or grants. Although the total amount appears large, it is only because the size of the industry is but dimly understood. Actually it falls far short of the payments made to Governments and public utilities by the industry in taxation and in payment for various services. There can be no question that this subsidy has been of immense help to a very large number of farmers in enabling them to hold their position or to reduce the rate at which they were falling behind. In other cases the payment of the Commonwealth grant has provided some vestige of comfort and living standard to settlers who were struggling with all the difficulties of pioneering as well as low prices and adverse seasons. Full particulars concerning these grants have been furnished by an officer of the Commerce Department.

Probably the most important task of the Commission is to make a recommendation as to what form assistance should be provided in future.

SUB-MARGINAL FARMS.

Objection has been raised to previous grants because a portion of them may have been paid to farmers who are on land that is not suitable for wheat-growing or to farmers who are not efficient managers. Although this can only apply to a very small minority of the farmers representing a still smaller percentage of the productive capacity of the industry, it does indicate a possibility of waste which the Commission should endeavor to find the means of avoiding.

The amount of assistance paid in the form of bounty to such cases is not great. By far the larger amount of public money being spent without result in such cases is by State authorities in the form of advances to develop country which has since proved to be unsuitable or in advances to enable farmers to continue farming such land. There are cases which have been reported in both Victoria and South Australia (and which are paralleled in other States) where the total gross proceeds from wheat grown on certain farms has not only fallen far below the amount necessary to pay any return on capital or provide any standard of living for the farmer, but has been only a small fraction of the money actually spent on seed, fertiliser, and sustenance to enable the farmer to put in the crop.

In cases such as this the provision of further finance can only lead to the prolonging of a hopeless struggle in which the farmer and his family must suffer hardship and disappointment and the amount of money contributed in assistance become a total loss.

At the same time it must not be forgotten that during the clearing of land it must be cropped continually for years with very small prospects of good yields. To abandon these partly developed farms irrespective of their quality as sub-marginal would be indiscriminate waste of the work and capital already expended.

It is not considered that the Commonwealth is in a position to discriminate between the merits of a large number of individual cases. There is probably very little country which should be abandoned altogether. In the majority of mar-

ginal cases the enlargement of holdings so that the farmer would be less dependent on cultivation of cereals is probably in the best interests of both the settlers and the State.

In various districts and in various parts of the same district the size of holdings, which experience has proved to be necessary, will vary. In the same districts the difference between the results obtained by different individuals will vary almost as greatly. There are some districts where it is now obvious that the country has been permanently deteriorated by attempts to cultivate it. The perennial bush has been destroyed and the country has become subject to drift in times of drought. In some cases the remedy may be to change the land over entirely to grazing. In others the land, although permanently injured by being ploughed once, now requires periodical cultivation in order to maintain even its lower level of fertility for grazing. These illustrations of the contrasts and complications serve to show the Commonwealth is quite unequipped to discriminate between individual cases.

There is, however, an obligation to the taxpayer to see that as far as general application is possible, assistance is given in such a way that it shall not be concentrated upon the most hopeless propositions.

BUSHEL OR ACREAGE BASIS.

The provision of a bounty on production, such as that provided in 1931-2 (or through the medium of a home price as is suggested later), does spread the assistance on an industry basis roughly in proportion to the value of each section of the industry to the country. Over a run of years such a basis would average out so that the accidents of season, or other adverse circumstances, cancelled each other. For a single year, however, the provision of assistance on such a basis would have left a great many very hard cases where a crop had been destroyed by hail, fire, flood, or an exceptional season, without any assistance at all. Individuals so missed were certainly those who would require assistance most urgently.

Arrangements with the States were therefore made during the last two years to grant assistance substantially on an acreage basis. This basis, although in a rough and ready way the most effective for short period salvage in the industry, would undoubtedly be open to abuse if made as a regular practice. There has already been a small amount of land lightly cultivated as a catch crop because of the likelihood that payment of a bounty on an acreage basis would ensure a return to cover the meagre outlay for such inferior farming. Any encouragement of extension of this practice is clearly most undesirable.

RESTING LAND.

Further, the payment of assistance on an acreage basis is a direct discouragement to the resting of land. Although it is considered impracticable to compulsorily reduce the acreage on a quota basis, there is no doubt that, if it were not for the debt structure, a great deal of land would be voluntarily diverted from wheat growing to other purposes.

In many of the older farming districts where cropping has been continuous for 30 or 40 years a reduction in the fertility of the land has taken place. It is found that resting the land for a few years restores that fertility, and the increased yields from land cropped after a period of rest go a considerable distance towards making good the loss of turnover incurred while the land was being spelled. The number of extra livestock which it is possible to carry on the uncultivated land contributes a substantial amount to the overhead commitments of the farm, but where the debt structure is considerable the farmer is not in a position to afford to reduce his turnover at all. The highly commendable

anxiety of farmers to meet all their commitments has led to farmers cropping the utmost possible area which their plant and time would allow. Although it is obviously a desirable time to rest land from wheat farming when the price of wheat is low, the low price makes it more difficult for the farmer to exist on the smaller turnover. Receiving a bounty on what he produces may make all the difference and influence the farmer to change to a better rotation.

The payment of assistance on an acreage basis also encourages the farming of the greatest possible area. The effect of this can be plainly seen in a deterioration of the Australian sample of wheat, more and more of which is being grown on partially exhausted land or upon stubble ground or inadequately cultivated land.

Roughly, the Commonwealth cannot be expected to discriminate between the quality of individual farms or farmers. That must be a matter of State administration. It should, however, be assured that the States are not using funds provided by the Commonwealth to prolong the hopeless struggle on uneconomic land. Subject to that where in place of a home price assistance is provided out of revenue the minimum of restriction should be placed upon the State in the way the money is employed so that the variety of cases can be provided for in such a way that the best and most effective method of working the land is not discouraged.

SIZE OF HOLDINGS.

In the case of obviously sub-marginal farms the problem in practice is very much more one of repatriating a proportion of the farmers elsewhere so that the size of the holdings can be increased to give a more balanced and stable livelihood.

Over most of the wheat belt farms are an adequate size. In Western Australia farmers' difficulties are even increased because the average holding is larger than can be developed with the capital which the average farmer can obtain. But there are places in the Victorian mallee and in Upper Eyre's Peninsula where holdings have proved to be too small. Besides these particular congested localities there are scattered all over the farming districts many returned soldiers' settlements where the farms are much too small.

The extent to which Commonwealth might co-operate with the States in financing the cost of repatriating these farmers and also the cost of providing water, fencing, &c., for an alteration in the uses to which the land is put are things which should be considered by the Commission as the lines supplementary to a bounty along which Commonwealth funds might be usefully employed in assisting the reconstruction and re-establishment of the wheat farming industry.

SIDE LINES AND ALTERNATIVE CROPS.

In considering the question of what other crops offer profitable alternatives to wheat growing, the Commission will find that conditions vary between every district and almost every farm. As a matter of general principle, it can be stated that diversity of production, as far as any particular farm is suitable for a variety of products, makes for stability and spreads risks. It is better for the farmer, as for any other investor, not to put all his eggs in one basket. On the other hand, there is seldom much advantage in switching simply to chase the market after some other product than wheat because its price happens to be relatively higher at the moment. By the time a change over is completed market conditions have usually changed also. Wheat farmers and graziers who have gone in for dairying have helped first to put up the price of cows and then to bring down the price of butter. There is little doubt that the present satisfactory price of lamb would be quickly depressed by any considerable increase in the supply.

In addition to this there is a possibility of the market for dairy produce and lamb being curtailed by quota limits to their entry into the British market.

Table C shows the price movements of alternative products up to June last year. Since then wool and lamb have improved and butter fallen further in price. The outlook for wool is reported to be sounder at prices above those of recent years, although not at the high present level. Some sheep on a farm are almost always an advantage to the cultivation irrespective of the price of wool or lamb. The urge is therefore strong to increase their number when the price is attractive. At the present time it is only the high price of sheep and obstacles of finance, limited areas, shortage of water, or incomplete fencing which are likely to prevent less fortunate or less established farmers from diverting some of their resources from wheat to woolgrowing or lamb raising. A number of institutions have been assisting farmers to buy sheep where the investment was sound. Further action by Governments outside the ordinary channels might easily cause a rise in sheep prices similar to that of land values during the time when Governments were buying land for returned soldiers, or to the rise in the price of draught horses when the various State farm relief authorities were assisting farmers to replace their tractors with horses. Where wheat is grown on a regular rotation there will be an effort made to lengthen the rotation between wheat crops so as to reduce the area on the farm actually seeded each year to wheat and replace it with fodder crops or specially sown or self-sown pasture. It has already been suggested that the Commission should advise as to the extent Governments can assist this tendency.

FLOUR TAX.

But when the dismal price outlook is considered and the very great political difficulties in obtaining an adequate reduction in costs, it appears that something more stable than doles is required to support the industry until world conditions improve.

The morale of farmers is being lowered by the annual petitions which it is necessary to renew for assistance. The reaction in Parliament and antagonism on the part of other sections of the community has all an unsettling effect, and is creating a sense of injustice among farmers.

In a few places something approaching demoralisation has been reached. Desperation and sense of injustice have banded whole communities together in desperate remedies which can only do harm to the general body of farmers.

Mortgagees' sales have been boycotted. Attempts have been made to hold up deliveries of wheat. Public opinion in some localities is growing more lenient towards the farmer who is not doing his best for his creditors because he has no hope in the future. The overwhelming majority of farmers in the great majority of districts have remained proof against such temptation and are sweating and skimping in order to pay their way, but when there is a sense of injustice there is always danger of infection spreading.

In comparison with the desperate, though ineffectual, actions of farmers in the United States and other countries the steadiness, the perseverance, and the high standard of citizenship of Australian farmers forms a striking contrast.

The almost general Australian practice has been to guarantee to efficient Australian secondary industries a price for their product to enable them to maintain an Australian standard for the people engaged in the industries. The bounties and grants to wheatgrowers have not been made on this basis, except to the extent which part of the grant made this year has been financed by a flour tax.

The raising of funds for farm assistance through a flour tax is the logical application of the almost general Australian practice, but because it is applied under the name of a tax it meets with bitter antagonism. Altogether, apart from the sentimental objection to a tax upon flour, economists have pointed out that

its effect upon the cost of living, and thereby upon the basic wage, exaggerates its effect upon consumers and also causes a great part of its cost to fall back upon the export industries. This is probably the case, but it has not been made any bar to the making of laws and awards to govern the return to wage earners in the milling and baking industry which equally affect the price of bread and the cost of living.

The protagonists of the consumers appear to be seeking rather a ghoulish advantage from the little cheapness obtained in bread stuffs as the result of the ruinous low liquidation price of wheat—the raw material of bread. This must be a fleeting advantage, part of which must be lost as soon as bankruptcy of farmers and deterioration of land and plant have adjusted the supply of wheat to current demand. It is quite distinct from the ever desirable cheapness derived from better or more economical methods.

Further, in Australia there is a growing feeling that the fall in nominal wages has reached a point where it is seriously lowering the standard of living as measured by comforts not included in the items from which the cost of living index is computed. The case of the wage-earner who is purchasing a house on long period agreement is particularly embarrassing at the present time. For these reasons there has been a growing tendency in more fortunate industries that can afford to ignore costs not to apply in all cases full reductions made in awards as a result of falls in cost of living index. Therefore any compensation to farmers through lowered costs because of bankrupt wheat production appears problematical and remote.

HOME PRICE.

Some of the economic and most of the sentimental objections to a flour tax apply with much less force to a Home Price for wheat milled for consumption in Australia. The home price for wheat would give some stability in the value of millers and bakers' stocks. To that extent it would reduce the risk which they have to face in the fluctuations in the value of stocks and might make it possible for them to work on smaller margins. Furthermore, the home price would remain stationary, and, as the world price of wheat rose, the amount of the subsidy contributed through the home price would correspondingly reduce. It would act as a balancing point to provide assistance in some proportion to its need, and be no drain upon the public at times when assistance was not required.

There are no complaints but only rejoicings about any rise in the cost of living due to increased wool prices. There would be none were the price of wheat to rise in the world's market. Although in both of these cases the proportion of Australian output which is exported is so much greater than that consumed locally that a rise in the world price brings several pounds into the country for every pound which it costs the Australian consumer, this does not apply to the price of meat, of which only a small proportion of the output is exported.

During the last 18 months the price of export lamb has approximately doubled, and this has taken with it the price of mutton and lamb slaughtered for consumption in Australia. Although only a very small proportion of sheep and lambs killed in Australia are exported, there is general satisfaction that the rise in the price of meat has tended to lower the gap between the price of one form of primary production and that of average secondary goods.

The Commission will have the duty of giving advice as to what is a fair home price.

It is pointed out that this is substantially higher than the bare existence costs of the industry at a time when it is in the condition of a sweated industry. Figures have been published in South Australia of farmers who have been working under the Debt Adjustment Scheme. Unlike the farmers working under the Farm Relief Law, these farmers are from good established districts as well

as the pioneering districts. They have sought protection under the Debt Adjustment Law in most cases because of pressure on the part of one or more of their creditors, which appeared to the Judge to be unreasonable. Their accounts have been rigidly supervised now for two years. It is plain from this that the average cost on the bare existence level is something over 3s. per bushel during the two seasons in which yields per acre were well above the average. In average seasons the cost per bushel would be higher. It is probable that this can be taken as a fair average for the whole of Australia as about the price which is needed by the average farmer for all the wheat he sells in order to maintain the struggle for solvency in similar seasons.

BASIS OF HOME PRICE.

This figure represents a sweated standard in comparison with that adopted as reasonable when assistance, whether by Tariff or Bounty, is being considered for other industries. In deciding what is a fair price for Australian-made manufactures the Tariff Board allows for wages at Australian standards and for reasonable interest upon invested capital. On this basis of cost an estimate is arrived at as to whether the value of the industry is great enough to warrant the cost to the public of keeping the industry going. It is only fair that the same standards should be applied to the wheat industry. By stinting and struggling, the average farmer can hold his own with a lower price—probably in the region of 3s. a bushel at sidings, provided he gets that price for all his marketable wheat. As the price to-day is more than 1s. a bushel below that figure, it is only by receiving a price equivalent to that of other industries for the proportion he sells for local use that his return can be averaged up to anywhere near his unpostponable expenses. At present prices quite a low home price would amount to valuable increase per bushel all round. This would not be enough to maintain sub-marginal farmers in uneconomic production. It would, however, enable a great many farmers by stinting themselves and postponing replacements to hold on for a time and reduce the rate of retrogression everywhere that wheat farming has any sound future.

Some farmers, either because of exceptional efficiency or especially good land, produce more cheaply. On the other hand, there are others whose expenses per bushel are higher. This diversity in the conditions of production from the land is inevitable, and should not be a bar to the granting of help similar to that given to the dairying industry and to others, on the basis of the average. Reasons have been given earlier why assistance on the basis of wheat grown is desirable, and it is considered that of all the alternatives the provision of means to ensure a fair home price is the most equitable.

MARKETING.

The means by which a home price can be made effective raises the highly controversial question of marketing. A great many farmers do not approve of the principle of a compulsory pool. They like to retain the alternative methods of disposing of their wheat which the present system of open market sales, storage, or voluntary pools offers to them. They would be reluctant to lose the competition which at present arises from there being several wheat buyers in every yard. A compulsory pool, although it would mean only one buyer, would make the establishment of a home price for home-consumed wheat a simple matter, and there is little doubt that if there were no other way to obtain a home price, the need for it would outweigh the objections of many farmers who do not favor a compulsory wheat pool as the best method of marketing wheat overseas.

There are several methods by which a home price can be established without suppressing the open market for export. The Commission will doubtless receive explanations as to their details.

The simplest would be an adaptation of the English system. In England the mechanism is necessarily more complicated because only a fraction of the wheat gristed is home grown and eligible for the home price. Each season it is necessary to ascertain what that fraction is and then to place upon every miller the obligation to absorb that percentage of the home-grown wheat either in his own grist or that of another miller. Since millers use various proportions of the different types of wheat from many countries according to the "mix" they require, the rights and obligations are necessarily negotiable. Each miller is able to satisfy his obligation towards home wheat and establish his rights to grist whatever mix of imported or home wheat he desires, once he has completed payment of the guaranteed home price for his share of home-grown wheat. This he does by paying to the Administering Authority the difference between the market price and the guaranteed home price. These payments build up the fund from which farmers receive deficiency payments about equal to the difference between the guaranteed price and that for which they sold their wheat in the open market. The wheat and flour trade goes on as before.

In Australia only home-grown wheat is ordinarily gristed. All the complicated arrangement of quotas is therefore unnecessary. The home price would apply to all wheat milled for home consumption, and provision would be made to exempt under proper security wheat milled for export flour. Millers would be required to make deficiency payments as in England, and these would be distributed to farmers on the basis of the quantity of wheat each had marketed. The export trade and the sale of wheat for fowls' feed or livestock could go on as before at world-price levels.

But if the mechanism required for Australian conditions is simpler than in England, the constitutional requirements of Australia are more complex. Both State and Federal legislation would be required. It would be necessary to set up a board in each State in order to establish a home price and to collect from the millers the difference between it and market price because these are in the main matters of intra-State trading. A Federal Board would also be necessary to regulate interstate transactions which might otherwise defeat the action of the State Boards. The Federal Board should also have the responsibility of distributing the deficiency payments to the growers on an Australian basis.

It is considered that a majority of the members of these boards should be growers' representatives and that representation of merchants, co-operative pools, millers, and consumers should also be provided for.

Most of the Australian systems of marketing or local price stabilisation are made legally effective by the provision of a quota according to which participation in the privileges of the local market carries with it a liability to share proportionately in the responsibilities of export. It is not certain whether this is due to the stages of evolution through which the systems have grown or to a real necessity which arises from the limits of the constitution or merely to a political weakness for complicated and imposing fandangles. As far as mechanism is concerned Australian export quotas, provided they were negotiable like the English milling quotas, could be similarly applied to the Australian wheat trade. In themselves they would only mean restrictions and complications without any economic benefit to farmers, millers, or consumers. Unless the Constitution renders them essential there is no sound reason why they should be adopted for the wheat and flour industries.

CONCLUSION.

The most effectual and the most lasting relief to farmers is that which takes the form of reducing for them costs of production and of transport over which they have no control. The most onerous and the most universal of these are interest, taxation, rail freights, shipping charges, and the expense of farm requisites. Their incidence and the possibilities of its reduction have been discussed.

There are also a number of other problems of expense peculiar to certain States or certain types of farms. The prospects of economy through a change to bulk handling is one. The establishment of a more elaborate grading system, the best quality and size of cornsacks, and the standard of fertilisers are others. The scale of agents' fees and charges for lumping and handling are of appreciable importance. The safeguarding of property rights over wheat in storage becomes an acute problem at times. The scale of Crown rents and the method of assessment for land tax valuation are of serious importance to many farmers. There may be possibilities of cheaper tractor fuel by the use of producer gas in place of kerosene.

There are continuous questions always before those interested. The bad times have made them more alive and may speed up their solution. The Commission will no doubt hear about them and consider them.

Each of them is a fairly extensive technical question by itself.

The main task of the Commission is to advise upon the extent to which the problems general to the industry can be dealt with; upon the extent to which those costs affecting the major part of the industry can be reduced; whether the world price of wheat can be raised; and the best form and the extent of assistance needed, whether by provision of an Australian price or bounty, to enable the farmers to keep going during the period of reconstruction. Reasons have been given at length to show that the provision of a home price is the most equitable and the most effective.

NOTES.—(A) Imported wheat. (B) Unweighted average of daily quotes. (C) Price officially fixed on trucks Sydney of bagged wheat for flour for home consumption, 1915-1921. (D) As from 1922 shippers' and millers' prices bagged on trucks Sydney. (E) Weighted average price of wheat (harvested in season ending in year shown in first column) delivered at country railway sidings and elevators after deducting net cost of bags. a. Voluntary Pool price.

The Sydney prices quoted are per imperial bushel (60lb.) f.a.q. wheat in 3bush. bags. The bag is sold with the wheat and is included in the weight paid for as wheat. The monthly averages represent the mean of daily prices, and the annual average is the mean of the monthly averages. Formerly practically the whole of the wheat marketed was in buyers' hands before the end of March, but in recent years the practice of pooling, and more recently still the introduction of the wheat elevators and storage by farmers have extended the period of marketing.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

**DELIVERY.—CHICKS—July to September.
EGGS—July to September.**

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

IRRIGATION WATERS FOR HORTICULTURAL PURPOSES IN SOUTH AUSTRALIA.

[Address Broadcasted from 5CL by GEO. QUINN, Chief Horticultural Instructor, on February 20th, 1934.]

These southern parts of Australia lie in what may be termed the warmer temperate belt of the continent wherein the yearly weather cycle consists of a cold and more or less rainy season, followed by a dry, hot summer period of fully six months' duration. The only summer rains which may fall consist of thundershowers received at intervals usually too widely separated to prove dependable.

It is during this long summer season that the need for an adequate supply of soil moisture becomes the dominant consideration in the successful production of horticultural crops, whether they be fruits, vegetables, or flowers.

It may be briefly stated here that water is essential to the wellbeing of growing plants inasmuch as it maintains the turgidity of the leaves and more tender shoots and tissues generally. It is also the great solvent of mineral salts in the soil, including those which go to form the necessary plant-building materials which the plants can procure from the soil only. Finally, water is the only medium whereby these solutions of mineral salts may enter the roots and traverse the sap stream to the leaves, and from thence as elaborated sap be passed throughout the plant and thus enable it to make accretions to its growths in both roots and branches.

Realising the above simple facts, it becomes evident that to obtain the maximum results from crops in our climate, at no time during the active growing period of these crops should the volume of soil moisture fall below that point which is sufficient to prevent the plants wilting and remaining in that state over any appreciable period of time. To achieve this desirable condition the command of an adequate supply of suitable irrigation water becomes a necessity for the effective growth of all garden crops during our long dry summer season.

The sources from which supplies of irrigation waters are obtained in this State consist of:—

1. Running streams.
2. Wells and bores.
3. Reservoirs and dams.

RUNNING STREAMS.

With the exception of the Murray River, this State can boast of no permanent streams as sources from whence large supplies of good irrigation water are available at all times in the summer season. This happy condition did not always exist even in the favored Murray Valley, as for many years prior to the locking of the stream the older irrigation settlements suffered from periods of scarcity of supply, combined with a dangerous degree of salinity in the small quantities available.

In the coastal country all of those streams which have their rise in the Ranges east of St. Vincent Gulf, and during the wet season discharge floodwaters into the Gulf at various points, as the summer advances shrink to mere trickles between widely separated waterholes. It is unfortunate that with this falling supply there also comes a rapid rise in the salinity of the water. In those streams which run into the sea not farther north than Adelaide this deterioration in the quality of the water does not extend beyond the tolerance displayed by most horticultural crops. The supplies in those streams, however, which during

the winter discharge floodwaters into the Spencer and St. Vincent Gulfs at points north of Adelaide, by mid-summer invariably reach a degree of salinity which renders their prolonged use highly dangerous to any other than the most salt-tolerant plants.

WELLS AND BORES.

The water supplies derivable from wells and shallow bores vary greatly, both in volume and suitability for garden purposes. Many of those sunk to depths of between 25ft. and 50ft. on the Plain which stretches from Adelaide northwards, frequently yield a sufficient volume of water to supply a good many acres of orchard or market garden. The greater number of these may be found on the Plain between Adelaide and its western and northern suburbs and the coast. On the eastern side between the city and the foothills of the Mount Lofty Ranges the wells and bores usually have to be sunk to a greater depth to obtain a desirable volume of water. In numerous instances, however, the water is more suitable for supporting plant life. This is particularly so when the supplies are found in the gravel strata which have been formed over the beds of long-obliterated water-courses which ran from the Ranges into the main outlets to the sea. On the western side of this Plain the water is found in the sands or deep clay belts which form the subsoil. Generally, waters obtained from deep bores—200 to 500 or more feet in depth—are less saline than those obtained in the wells or shallow bores. The source of the latter supplies would appear to be a more local one, such as from soakings of winter rains which have fallen on the Plain and percolated through the somewhat saline soil into the rifts below.

As far as investigation has proceeded in respect to the waters obtained from wells and bores sunk in the semi-arid and arid parts of the State, the further inland one goes usually the greater becomes the salinity of the average water. A few wells, however, have been found yielding waters peculiarly low in salts injurious to plants. Outside of those regions which receive from 25 inches and upwards of rain annually and then mostly falling during the winter months, few wells are found which yield irrigation waters highly suitable for permanent use on land devoted to garden crops.

RESERVOIRS AND DAMS.

The quality and quantity of the waters obtainable from reservoirs and dams depend on the extent of the rainfall and the nature of the soil over which the run-off takes place. The lower the rainfall the lesser usually is the volume of water that may be conserved, and almost without exception, the lower the rainfall the higher the saline content in the surface of the land off which the water is collected.

The public supplies reticulated from the Government reservoirs to the metropolitan areas and country districts for nearly a hundred miles northwards represent the purest forms of irrigation waters available throughout the year in this State. The waters in at least two of the large reservoirs in the more northern and western districts reveal, however, the very saline nature of the soil off which they are collected and in practical use they have proved very indifferent irrigation supplies for horticultural purposes.

In some hilly districts of good rainfall in the Lower North there are ample opportunities for individual horticulturists to conserve irrigation water in privately excavated surface dams—as has been demonstrated by some of the more enterprising settlers in those localities. At Doncaster, which is a large fruit-growing centre a few miles east of Melbourne, a splendid object-lesson has been given to Australia of what could be done by a vast number of individual settlers in providing themselves with a supply of irrigation water in this manner.

DEPARTMENTAL RESEARCH.

For upwards of twenty years the Officers of the Horticultural Branch of the S.A. Department of Agriculture have been constantly studying this question in conjunction with the practical horticulturists and aided by the skill of the staff of the Government Department of Chemistry. The qualities and quantities of the water used on the different crops, the nature of the soils and subsoils, and the methods of applying water to the land, have been duly taken into consideration, when noting the results in crop production under irrigation which has been in operation for many years.

In the course of this work a vast number of samples of irrigation waters have been analysed and their saline contents recorded. The results of these observations enable us to form a fairly accurate opinion of what will be the effect of irrigating any specific garden crop of vegetables or fruit trees growing in a soil of known character, under known rainfall conditions, and using a water, the salinity of which has been determined by analysis.

FORMS OF INJURIOUS SALTS.

The principal salts found in solution in the irrigation waters used in the chief gardening centres of this State consist of lime salts, such as the carbonate and sulphate—the latter commonly called gypsum. These, unless in excess—which is seldom the case—are not harmful and may under certain soil conditions often prove valuable.

The salts of sodium chiefly consist of the chloride or common salt and the sulphate or Glauber salts, whilst those of magnesium are the chloride known as Bittern, and the sulphate, which is the well-known Epsom salts. Of the salts of sodium and magnesium, the chlorides are frequently the most abundant, as well as being the most injurious to plant life. The sulphates are also undesirable, but to a much lesser degree than are the chlorides.

In the investigations previously referred to it has been ascertained that when used on soils permitting free percolation, and in a district receiving good rainfall—from which 12 to 15 inches fall during the cool winter season, thus assisting in cleansing the land—irrigation waters ranging as high as 82 grains of the injurious salts per gallon, 60 of which may be chlorides—may be used without unduly impregnating the soil in so far as the growing of most kinds of kitchen vegetables or fruit trees are concerned. This quantity of 82 grains per gallon represents 1lb. of the injurious salts in each 85 gallons of the water.

When the irrigation waters contained from 100 to 140 grains of these injurious forms of salts per gallon, even when used on fairly well-drained land, the growing of French beans and cucumbers became impossible, and citrus trees proved unthrifty and declined after a short period of years. These latter quantities are equivalent to 1lb. of the injurious salts dissolved in 69 and 51 gallons of these respective waters.

In conclusion, I wish to remind you that these more highly saline waters themselves would not injure the plants from their direct application to the crop, but when they have been applied for several years to the ground during the warm seasons, it is then that, in the words of Hilgard, the great Californian authority, "inevitable accumulation" begins in the upper layers due to the process of evaporation. That portion of the irrigation water which has not been absorbed by the crop and does not get away *via* the under-drainage, is drawn back by the sun's heat close to the surface, whence it passes off into the air as vapor, leaving the salts behind in a solid crystalline form in the land. When the accumulation of injurious salts has thus reached a stage when the rain or irrigation water may form from them a solution too concentrated for the crop then in occupation of the land to tolerate, the plants soon cease to function and death quickly ensues. They often appear to perish of thirst though standing in a soil showing abundance of moisture.

SHEEP IN THE DRIER MALLEE FARMING AREAS.

[By W. H. BROWNRIGG, H.D.A., Agricultural Instructor.]

With the extension of farming into the drier mallee areas of this State in recent years the importance of combining sheep with wheat farming is becoming more evident every day. The mallee farmer realises that the more uncertain the rainfall the more essential becomes firmly compacted fallow, and as it is unwise to overtax the land, either by overworking the machine or continuous cropping with wheat, sheep must be used to get the maximum returns from holdings. The cost of production is becoming one of the greatest problems of the farmer to-day, and whilst there are many outside agencies over which he has no control there are still many ways by which the man on the land can reduce his costs. By utilising stubble feed that would otherwise be wasted and practically enforcing a wider rotation the sheep is of paramount importance when connected with farming. It has been proved unwise to fallow the same land more often than once in four to five years in these dry areas of light textured soil, and as rent is paid every year on every acre some use must be made every year of every acre. This cannot be done without depasturing stock of some kind, and for the conditions prevailing in the Mallee areas of South Australia sheep have proved themselves the most suitable stock to raise.

CLIMATIC CONDITIONS GOVERN BREED.

A farmer intending to run sheep should carefully study the climatic conditions before deciding on which breed of sheep to keep, but for the most of the Mallee areas of South Australia the Merino has proved itself the most suitable, not only on account of its hardiness and adaptability, but because the farmer, owing to lack of markets and easy and rapid transport facilities, is forced to be mainly a wool producer.

TYPE OF MERINO.

The most suitable type of Merino for farming areas is the large, plain-bodied, robust sheep which boasts of that great essential "constitution," and a sheep which is common to this State, having been brought, by careful breeding by stud masters, to a state of excellence rarely found in other parts. This sheep carries a strong frame, well fleshed and symmetrical, and is covered with a fairly even type of strong wool, showing good character and length, yielding fairly well a profitable wool of 60's to 64's standard count.

BREEDING EWES.

Type was lightly touched upon in the previous paragraph, but some advice on what constitutes a good breeding ewe and a description of it is necessary.

When launching out into sheep breeding, or when a farmer wishes to replace his existing flock of small, unthrifty, unprofitable sheep, he should avail himself of those that are annually offering off-shears on the surrounding pastoral properties. He should endeavor to get a line of "cast for age" ewes. It is not necessary for him to rely wholly on his own judgment, because if the sheep carry the station ear and age mark he has the knowledge that they were on the station for three or four years. Carrying the station brand and ear mark is sufficient evidence that the sheep must be good mothers, strong of constitution, of suitable type carrying a profitable covering or they would not have survived the annual culling until they were full mouthed. A ewe cast for age is really not a cull in the true meaning of the word, and cannot be likened to young sheep that are annually culled on a station. The latter are culled as being unsuitable owing to some defect in either conformation, constitution, or covering, whilst the cast ewe has to make way for the suitable young sheep coming on. A profitable breeding

ewe should be large in size without coarseness or masculinity; with clean, alert face; good neck without over development; broad, deep chest; well-sprung ribs; even, broad top line; roomy abdomen; reasonable length between loin and tail; wide breech; an even udder without dummy teats, and should stand firmly on her feet with straight legs. The points touched upon are mainly to impress the importance of thrift and constitution, and a ewe possessing these qualifications will have this essential hardiness. The wool or covering should be the correct length for the time the sheep were shorn, and should be evenly distributed over the body, showing good character and evenness, realising, of course, that toward the breech a little stronger wool must be expected, but a great variation should not be accepted. The points should be well covered, wool coming to the knee in front and below the hock in the hind legs; the face should not be shut in with wool, but wool should grow on the head up to behind the eye and on the jaws. Body wrinkles should be absent from the shoulder back as the absence of tail and breech wrinkles is essential. Where possible, intending farmers should arrange to inspect the sheep in the wool with the idea of taking delivery off shears, and it is a good principle for farmers to join together and purchase a line of ewes with the idea of taking a "run" each of the number required by each individual.

THE TYPE OF RAM.

Having purchased suitable ewes the next essential is to purchase the most suitable ram for mating purposes and too much care cannot be exercised in this important branch of sheep breeding. It is a mistaken idea that the price paid for the ram is the guiding factor. Rams of the wrong type costing fifty guineas would not be nearly as suitable as rams of the correct type costing three. For general breeding in the Mallee areas the large framed, plain bodied South Australian Merino has no peer, and when a suitable ram from a breeder is purchased and a satisfactory improvement is seen in his progeny no introduction of new blood should be thought of except, after breeding for some time, a defect exhibiting itself, is to be overcome. Here again, farmers in a district can join together and buy a number of rams which could be exchanged among themselves, so preventing them going back on their own stock and thereby lengthening the usefulness of these rams. Briefly, the two main points to be looked for in purchasing rams, are suitability for the ewes to be joined and constitution. Because a man sees the farmer's wool in the saleroom, it does not follow that he can purchase the right type of ram for the ewes producing that wool, as many other essentials have to be considered. When buying rams farmers should keep in mind the following descriptive points:—*Head* nicely set on, carried well, face clean, nose showing masculinity without being bumpy, eyes large and alert, nostrils broad and open, mouth large, lips firm and teeth even, neither under nor overshot. *The horns*, thick and strong at the base, should curve evenly and slightly away from the head with an attractive sweep, good color and texture with even, broad ridging. (Fine, thin horns are signs of bad breeding, low vitality; and close horns interfere with shearing.) *The neck* not too short and cramped looking, carried well and evenly set on the shoulders with three well-balanced, well-carried folds, exhibiting character and breeding. *Shoulders* evenly placed for easy grace of movement with the blades not reaching too high at the withers. *The withers* broad and even, not unnecessarily high. *The back* short, broad with no tendency to dip. *The loins* broad, strong and level, joining evenly to the hind-quarters. *The hindquarters* should be even, of fair length from hips to tail, exhibiting no wrinkling about the tail and breech. *The legs* should be set well apart, giving plenty of room for width in both breech and chest. *The underline* should be even, neither exhibiting poddiness nor the reverse, i.e., greyhound appearance. *The chest* having a great depth and width for easy heart and lung action is always to be

looked for. *The covering* of a good Merino ram is of the utmost importance because although quite an amount of the good qualities in breeding go down the neck, Merino sheep are kept in the main for the return in wool that is expected. The sire's wool has a distinct masculine appearance and feel and should be of the correct strength to maintain the heavy cutting qualities of his progeny. The robust type of ram advocated carries a heavy fleece of fairly strong wool of somewhere in the region of 60's, standard count, which is evenly distributed over the body without too distinct a variation between the shoulder wool and that found on the hindquarters from the hip to the hock.

BREEDING.

Every farmer knows that the gestation period of a ewe is 150 days or approximately 5 months. This being so and with the knowledge of the vagaries of his particular district the farmer can calculate when the rams should be joined in order to have the lambs dropping at the most suitable time of the year, *i.e.*, when green grass should be plentiful. For example if rams were joined early in the second week of January, lambs should be expected during the first week in June. Ewes to be joined should be in a strong, healthy condition, not carrying an over-abundance of fat and, where possible, a fresh paddock or distinct change should be aimed at in order to encourage the ewes to come in season rapidly and ensure a fairly even drop of lambs. The rams in good, hard condition and in good heart—2 to every 100 ewes—should be left in with the ewes for a month or six weeks and then removed and placed in a good paddock by themselves and well tended until required next mating season. Quite a number of complaints are heard regarding rams which come from the studbreeders but as good flock-rams are generally purchased at the hogget or two-tooth stage farmers should realise that this is always the most difficult stage in the rearing of sheep and far better treatment should be meted out to them than they usually receive. Wherever possible, rams should be bought early, taken on to the farm and a little additional feed, such as oats, given until they recover from the shock of being transferred from the better conditions under which they may have been bred and become acclimatised to the conditions under which they are expected to work. As the sire is "half the flock" much more attention should be paid to this side of sheepfarming.

CARE OF THE PREGNANT EWE.

The ewe which is expected to nourish, give birth and feed a lamb must be looked after in order that she may do the work profitably. As it is necessary to keep her own strength of body above the constant drain caused by the lamb she is carrying, she must have enough to eat to maintain this condition. Where fodder can be grown cheaply, such as oats, no ewe should be allowed to get into low condition and with such labor saving devices as the Turretfield Automatic Feeders (particulars of which may be obtained from the Department of Agriculture) very little labor is required. Sheep will eat only what they require and at their own time without any jostling or knocking about. Pregnant ewes should be yarded, driven and worked amongst as little as possible but constant supervision such as riding through paddocks without dogs should be maintained. It is well to remember that a change of pasture now and then is very important with Merino ewes until they are transferred to the lambing paddock.

LAMB MARKING.

Lambs from ewes that have been well looked after should be reasonably strong and may be marked at any time from a few days old but preferably this should be done at from three weeks to a month. The operation is quite simple and consists of ear-marking, the castration of males, and docking, in that order. Suitable weather—that is, mild and not wintry—should be chosen and the work done early in the

day to enable the lambs to be mothered before nightfall. As many lambs are lost annually with tetanus, clean yards are very important and temporary yards erected in the lambing paddock reduce this risk. Cleanliness in the operation is very essential and all knives and earmarking pliers should be dipped periodically in a vessel such as a jam tin containing some disinfectant conveniently nailed to a post near the marking rail.

CASTRATION.

The lamb should be held firmly but not heavily on the marking rail by grasping the hind and fore legs on each side with the holder's two hands, the back of the lamb resting against the catcher's chest. There is nothing new in the operation, only to state that the top of the scrotum should be taken off with a firm cut, the thumb and forefingers of both hands being used to make the testicles protrude and both organs grasped firmly in the teeth and withdrawn. There are appliances on the market for withdrawing the testicles where a sheep man is unable or loath to do the operation with the teeth. There is another method, namely, bloodless castration, where properly constructed pincers are used which need not be described here.

DOCKING.

This is also done with a knife, and the tail taken off at about the second joint with one clean cut, the skin not being pulled tightly but preferably pushed toward the butt, so that it will cover the stump and assist healing. Some sheep men are in favor of dressings whilst others, where pastures are clean, do not consider them necessary.

MAINTENANCE OF TYPE.

A very important branch of sheep raising is to visualise an ideal sheep for the conditions, and to strive for that ideal. This is a natural gift to some people, and yet it is within the bounds of all if the practices of successful men are studied and carried out. It is not intended that this article should deal with stud breeding or blood lines except to impress on farmers not to make drastic changes in rams when new ones are required, but on obtaining a suitable type of ram from a certain stud breeder to adhere to that breeder's type. By this means evenness will be obtained both in the type of sheep and covering, making classing at shearing time a very easy matter. A critical eye should be cast over the young sheep that are to be kept as breeders, preferably at the two-tooth stage, and all young ewes should be discarded that are lacking in:—

Size, i.e., not making suitable growth for the conditions under which they were raised.

Constitution, which could be bracketed with the former. Lack of this essential is shown by under or overshot mouth, narrow wasty chest, grippy behind the shoulders, swamp back, narrow breech, drawn-up abdomen, and very fine bone or crooked legs.

Type.—The Merino is a highly bred animal evolved from poor type of sheep, and Nature plays peculiar pranks at times. Even in very good flocks "throw-backs" will appear, and these should always be discarded.

Wrinkles.—The aim of the South Australian breeder has been to produce a plain bodied, clean faced sheep, and any sheep showing heavy body wrinkles, especially about the tail or breech, or a woolly face should be discarded.

Covering.—As it is the main aim under Mallee farming conditions to produce wool, a careful examination of the fleece is necessary. Strong-woolled Merinos are not expected to have the density of the fine-woolled type, but a certain degree should be aimed at, and the fleece must comprise wool of length and character. Strong wools have to attain a certain length for their quality to be of the correct type, and character is denoted by crimps or waves on the wool fibres. Crimps are of great importance, and a wool exhibiting them from the skin to the tip is

termed a well-bred wool, and a straight wool is known as a badly-bred one. When examining the fleece on the sheep see that it is reasonably even in quality, not hairy around the breech nor wasty on the belly, and not lacking in the points.

Sheep that are lacking in the preceding points should be discarded and used for ration sheep or sold for that purpose.

HEALTH OF THE ANIMALS.

Disabilities and common ailments which can be controlled or lessened by the sheepowner are of great importance, and should, as far as possible, be prevented. Fortunately, our drier areas are very free from disease, and can easily be termed sound country, but even in the soundest areas certain ailments occur, the most important being:—

Blowfly Strike, which, although not absolutely preventible, can certainly be held in check by earnest endeavor. The sheep recommended in this article suffer least of all Merino types on account of lack of tail and crutch wrinkles. Again, sheep that are kept in a thriving and healthy condition are said not to expel foetid excreta so attractive to the flies. All female sheep should be crutched every year, not when the fly has started and the ewes are lambing, but as close up to lambing as it is safe, and to make one job of it the hoggets should be done at the same time. The method of crutching generally seen is very expensive as it is absolutely useless, and is expending energy and money to gain no end. The correct method to crutch sheep is to clean the wool from the back of the udder, clean out the breech, straight up the hamstring, over the tail, and down the other leg. When this method is used and the work done with machines the crutchings, if looked after, will pay for the work. A very good practice is to swab the crutch and tail with 1 per cent. arsenic solution, rubbing the mixture in well with the hand. This swabbing, if done correctly, will render the sheep practically immune for about four weeks. Another and more effective method, namely "jetting", necessitates the purchase of a plant, and is probably out of the realm of single farmers, but one could be purchased and used on a community basis.

Every farmer should have at least two fly traps, and all animal carcasses should be burned. The poisoning of rabbits over ground will always assist the fly menace. Sheepowners are advised to regard crutching and swabbing as of the greatest importance. Sheep should be kept in good health, and not yarded for lengthy periods. Further, a general and keen supervision should be maintained over the flock.

Worms.—There are many types of worms affecting sheep, especially from the lamb stage to the four-tooth period, and the main symptoms are unthriftiness, general wasting, in some cases profuse scouring, and finally dying of exhaustion. As the worm in the egg stage is taken into the alimentary tract off the grass and hatches out in the stomach, working into the bowels where it does the damage, a poison has to be administered in order to kill the parasite and prevent it reaching maturity, passing through the animal, and continuing to keep the country affected. The modern treatment for killing the worm is (1) carbon tetrachloride administered in gelatine capsules, 1 cubic centimetre for lambs and twice that dose for grown sheep, or the same drug in four times its quantity of liquid paraffin given by means of a syringe containing the correct dose inserted in the sheep's mouth, pushed over the tongue, and the syringe emptied steadily. Copper sulphate is used also, the strength being 2 per cent. solution and administered as a drench of $\frac{1}{2}$ oz. for lambs up to six months, increasing the dose by $\frac{1}{2}$ oz. for every six months until the adult stage is reached, when 2 ozs. or the maximum is used. Sheep should preferably be drenched in a standing position, and as a precaution drench two or three sheep with the mixture a day before the main lot is treated and note the result. The foregoing specifics tend to kill the worm, but good feed

and plenty of it will help the sheep to overcome and outgrow the ravages of the worm. Under our conditions the worm appears most seriously after a good season similar to 1932-33, when rank grass grew which was very poor in feed value. After such seasons and where sheep have been known to be affected as much grass as can be spared should be burned.

Contagious Ophthalmia or "pink eye" often leads to serious results. All animals noticed with one or both eyes running, if the trouble is not grass seed, should be isolated, and although it generally runs its course of seven to 10 days, recovery is hastened by dropping certain solutions into the eye twice daily. An effective solution is made by adding 5 grains of sulphate of zinc to 1oz. of distilled water.

Sheep Louse and Sheep Tick.—Both of these insects are to be found in the Mallee areas, and although not of very serious dimensions sheepowners are advised not to neglect the prevention of spreading, and should dip their flocks annually. The aim of dipping is to kill by poison the living insect on the sheep's body, and most poison dips contain arsenic in some form. A slowly dissolving dip has a more lasting effect than a quick dissolving one, and so has a better chance of remaining effective long enough to kill the tick or lice which hatch out of the eggs after dipping. Although not the best principle it is suggested that community dips be built and flocks can be run through easily because there will be plenty of labor available. When mixing dips do not rely on guesswork, but use a measure and stick strictly to the directions of the maker, as the requisite strength has been arrived at scientifically and is not improved by stronger or weaker mixtures. Use the softest water available, preferably rain water, and mix the solution carefully and steadily. Sheep should be dipped about a month to six weeks after shearing when sufficient wool has grown to ensure of the solution being held on the body. The sheep should not be overheated before being dipped, neither should dipping be done during extremely hot or cold bleak weather. With the bath kept well stirred the flock may be put through steadily, each sheep being pushed under at least once in the 25ft. swim.

On emerging from the dip sheep should stand in the draining pens till properly drained before turning out on to the pasture paddocks, and there is less danger from scald if the animals are dried in the shade.

Shearing Facilities.—Unnecessary time spent in doing any work adds to its cost, and as shearing is an annual business some thought should be given to certain essentials that will speed up and facilitate the operation. It is not suggested that owners of small farm flocks should build a separate shed for shearing, but the machinery shed or barn can be quite easily transformed and worked effectively. As the one objective is to obtain a wool harvest, and the more attractive the wool the better the price, farmers are advised to make a batten grating for one or two pens instead of the ordinary floor or ground which collects all excreta and becomes foul. It is usually necessary to have some sheep under cover every night, not only when rain is feared, but sufficient to keep the shearers occupied until the dew dries off the paddocked sheep. Any sheep left in overnight become dirty if not standing on grating. This grating can be made in sections so that it can be taken up and packed against a wall under cover when not in use. The pens can be made of cheaply but strongly constructed hurdles, which being also movable can be stacked away. The shearing board should be constructed of flooring boards and so placed that the catching pens are opposite the stands and the escape shute immediately behind, as it is easier to carry a woolly sheep across the board from the pen than scruff the sheep when shorn across to the shute. Light is an essential both over the board and wool table.

The general furnishings of a shed are simple, but should be so placed to give room, minimum of travelling, and effectiveness. The wool table may be placed at one end of the board, and should be 10ft. x 5ft. x 3ft. 3in. high, so placed that

it can be worked all round and not nailed on to one side of the wall. This facilitates the skirting of the fleece, as the parts to be taken off can be seen. Opposite the wool table four wool bins should be constructed 2ft. 6in. wide by 5ft. deep and at least 6ft. high. These may be constructed on a framework, using galvanized iron or washed super bags for partitions. Another bin, 5ft. x 5ft., may be constructed within easy throwing distance from the wool table to receive the skirtings, which can be looked through before baling. It is usual for farmers to use a skeleton or box press, which may easily be constructed by a handy man taking the size of the wool pack as a pattern.

Handling the Wool.—As about 25 per cent. of the wool grown in this State is made up of farmers' clips a serious move should be made in the direction of getting these clips up in a more attractive condition. Overseas buyers purchase wool on two main points, namely, quality and yield, and as freights to Europe are costly wools yielding less than 40 per cent. cannot be economically shipped. The meaning of "yield" is the amount of clean wool that can be obtained from a given quantity of greasy wool. For example, a wool of 46 per cent. yield would mean that from 100lbs. of this wool 54lbs. would be by-products and waste such as dirt, grease, &c. It can, therefore, be easily followed that overseas buyers cannot assess the yield of unclassified farmer's clips with sufficient accuracy to risk in buying, and in most cases they are bought at below their value by dealers who class them and resell them to a great advantage. It has been estimated that by not getting their wool up to better advantage farmers are losing from £1 to £1 5s. a bale.

Classing the Clip.—The average farmer imagines that this branch is far beyond him, whereas it is one of the simplest items of the wool harvest. There is no need to have a knowledge of spinning qualities, character, crimp, or elasticity as in big sheds; the farmer should separate the good, clean wool from the dirty and perished wool, and separate the heavy conditioned or yellow, gummy fleeces from the light, bright ones.

Skirting the Fleece.—The fleece should be thrown on to the table so that it spreads evenly with the shorn side down. All that is necessary in skirting is to remove the dirty portions around the breech, the hairy wool from the hook down, the black sweaty portions from the front and back flanks and, if seedy, the cheek pieces. This is done on both sides, remembering not to skirt deeply into the good wool as it is not necessary, and it robs the fleece wool.

Backing the Fleece.—In all Mallee areas, when sheep are run in connection with farming, the top or back of the sheep gathers and retains a certain amount of dirt which militates against the yolk, making the fibre fluffy, dry, parched looking, and in many cases tender. This wool must be separated from the bright portion of the fleece, and is taken out in the same manner as is used in skirting, being careful to remove all of the deteriorated wool. This leaves the two portions of good, bright, clean wool which, when tested with the fingers and thumb to see that it is not weak, is put in the bin to be used for the main or top line. Years ago it was thought that the fleece had to be kept intact, but under present-day conditions this is not necessary. If farmers called at their wool brokers and saw their wool that had been pressed backs and all they would not recognise it as the dirt has gone right through the wool, and it gives an appearance of a dingy, unattractive, low-yielding commodity.

The Backs can go with one lot which may also contain any tender fleece of the same type of wool. These should be branded "Backs."

Pieces.—The wool that is taken off in the process of skirting is picked over, and the dirty and stained portions separated from the cleaner and more attractive wool which can be placed in a bale by itself. The dirty portion should be dried in the sun if necessary, and mixed with the floor locks and baled separately. The

table locks will often contain a great deal of sand, and if so the present freight charges and price render them almost valueless, but can be spread in sheep yards to make a surface which is less dusty or boggy.

Bellies.—In small clips it is not necessary to make more than one line of belly wool, but all bellies should be skirted to remove dirty, draggy wool, and those from wethers and rams should be "pizzle rung," *i.e.*, taking the stained portion from the centre.

Classing the Fleeces.—The classing of the fleeces of the farmer's wool clip may be described as making the top line of the brightest, lightest, and most attractive wool and branding it for the sake of distinction AA. The second line will be made up of heavy-conditioned fleeces, which are usually shorter, and contain gummy yolk and have a yellow, unattractive, appearance, the short wool that could not go into the top line, and possibly the few other unattractive fleeces that are often found in farmers' clips. This line could be branded A.

Mixed Wools.—There will always be small amounts of wool which by themselves would not make a bale, and should form what is known as a mixed or composite bale, and a separating paper or bag placed between the different sorts.

Baling.—In the absence of a mechanical press an ordinary box press can be used, and is filled by tramping. Distorted and unattractive bales are to be avoided, and quite a good bale can be turned out by tramping, with a spade to assist in working down the sides and corners. An endeavor should be made to have the bales of fleece wool weighing about 300 pounds, and so apportion the wool that a "star" lot, *i.e.*, three bales and under, is avoided.

Branding.—The branding of the bale should be done neatly with ink, and not with paint or oily substance. A stencil plate should be used, which can be easily cut out of sheet tin or the sides of petrol tins, and once made will last for years. Freehand drawing with a paint brush usually makes a very unattractive job. The bale should be branded with the name or initials of the owner over the name of the farm, or the name of the farm is sufficient. The contents of the bale should be shown as AA or A or Pieces, &c., and it is not necessary to show it as Merino (usually shown as MO), as all wool is termed Merino unless marked otherwise. The number should then be placed on the bale. The relative positions of this branding are very essential, as certain places are to be used for buyer's brands. The bale is branded on the front and top, beginning with the farm name about the centre of the bale, the description of contents immediately below, and the number in a position about 8 in. from the side and bottom of the bale. Similar marking should be placed on the top of the bale or front flap. An excellent practice is to brand the bales immediately they come from the press, and enter in a book the number of the bale and contents.

Consigning Wool.—When consigning wool the broker should be advised stating the number of each bale, its brands, and contents, such as:—Bales numbered 1 to 7 contain the brightest and best wool; Nos. 8 to 12 the wool not considered suitable for the top line; Nos. 13 to 17 backs; No. 18 bellies; and No. 19 a mixed bale containing locks, stains, &c.; and Nos. 20 to 21 the best pieces. In this way the broker can handle the wool to full advantage, and bag lots or composite bales can be bulked with others farmers' bag lots, &c., and a line made which can be sold at better prices.

This article was written as a guide to farmers running sheep in connection with wheat. Many farmers are carried away with the price per pound obtained for wool, but should realise that the return per sheep is a greater guide. Briefly summing up, farmers should run sheep of the most suitable type; breed, feed, and cull with judgment, and exercise ordinary commonsense methods of placing the wool on the market in an attractive manner.

PAPERS READ AT CONFERENCES.

YORKE PENINSULA BRANCHES, PORT VICTORIA, MARCH 7th.

WOOL CLASSING.

[By R. O. CASTINE, Wauraltee.]

The present low price of farm produce makes farmers look about to find where they can save on cost of production, but for many years they have literally thrown money away through not making the most of what they have produced. When wool sales are in progress we hear that the farmers' clips—for the most part—are badly classed, and consequently, values are lower than would have been the case if care had been taken to match the wool before consigning it to the bale.

Wool classing means wool matching, and the art is to put similar fleeces together—that is, with the smallest amount of variation. Most farmers do their own classing, and a good many do not class at all. It is to these that I address this paper.

In the trade, wool is spoken of as 60s, 64s, 70s, 58s or whatever the case might be. This means that a 60's wool would spin 60 hanks of yarn each hank measuring 460 yards long, from 1lb. of scoured wool, free from noil.

The job in hand is to put the various counts into their correct classes, and to do this satisfactorily takes some practice. Wool is judged by crimp, length of staple, strength of staple, lightness, brightness, and boldness; in short, character.

Prepare for shearing in plenty of time. Clean out the shed thoroughly, as chaff and other foreign matter mixed with wool will always be looked at with disfavor by the wool buyer.

Have a good wool table, it can be made cheaply, and will greatly facilitate skirting fleeces. Make it sufficiently large so that the fleece spreads out well when it is thrown. Bins should also be provided to assist in matching the fleeces. Plenty of light and plenty of space is necessary to make the most of the work.

Procedure.—When the fleece is thrown on the table, skirt it lightly, taking care to take out only the sweaty edges, unless the fleece is very burry, then skirt deeper. Take care that fleece wool is not put into the pieces, or the pieces will not then be true pieces, but will consist of fleece and pieces. This may bring a fairly good price, but someone else will reap the benefit of having that fleece wool mixed in with the pieces.

Take out the back completely; the spindly back will show why this is necessary when in a bin alongside a bin of side wool. The side wool is the best, usually being shafty bright wool full of character, as compared with the wool from the back. Do not label the backs as such. Many buyers will not waste time in inspecting "backs," so, if a fine wool, simply brand it A, or, if a coarse wool, B. The side wools then may be branded AA if fine, or, if coarse, BB.

The top line of wool should carry the AA and comprise all the longest, lightest, brightest, and boldest fleeces of fine quality, free from breaks, and the BB consist of the longest, lightest, brightest, and boldest fleeces of coarse quality, free from breaks.

Make a cast line, or if the size of the flock warrants it, make more lines, but for general purposes, one cast line will carry fleeces with excessive yolk, tender, &c. Do not allow black wool to become mixed with the white, and always remember when classing that the buyer is out to see what mistakes have been made, and for every mistake the farmer makes he will base the price that he is prepared to offer accordingly.

If a wool-press is available, so much the better; if not, the old foot-press makes a fair job. Do not be frightened to tear the wool about, but make sure that each bale contains 250lbs. This is the recognised weight of a bale of wool, and anything over 300 is viewed with suspicion, and allowances are made for sand, &c.

Take notice of the brokers; they will keep you informed as to what the trade requires, and it is up to you to see that the trade gets what it requires. The brokers are out to make as much in commission as they possibly can, and it stands to reason that the more commission they obtain, the better the price is for the grower, so they will look after your interest, as it is surely their interest.

Brand bales neatly. Appearance means a lot, and the cost of a few stencil plates is comparatively trifling.

Summarised, I would advocate:—

1. Clean sheds, well drained, or gratings.
2. Plenty of light and wool-room.
3. A good wool table.
4. Skirt lightly; make one line of pieces.
5. Take out backs.
6. Brand fine side wools AA.
7. Brand coarse side wools BB.
8. Brand fine back wools A.
9. Brand coarse back wools B.
10. Make a cast lot and brand C.
11. Fasten bales securely.
12. Brand bales distinctly and use stencil plates.
13. Consign to some reputable wool-brokers, as their experts will give you some medium of protection on their valuation.

TRANSPORTATION OF SHEEP.

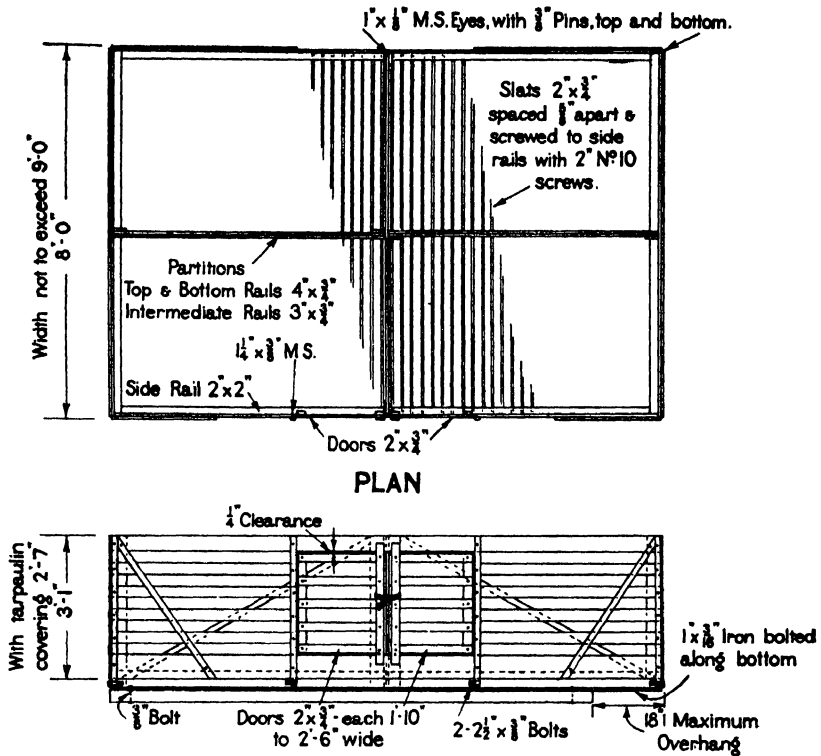

[By O. H. HEINRICH, South Kilkerran.]

Of the various means of transporting sheep, it is proposed to deal only with transport by motor truck.

The first to deal with, then, is the frame for the truck, and these again are divided into: (a) single floor frames; (b) double-deckers. The first thing to consider in any frame is the timber to use for its construction. All timber should be planed all round. Oregon is to be preferred to VDL—it is lighter, equally strong, and much nicer to work. Moreover, it will not twist like VDL and only costs 30s. to £2 more for a large frame, which is not a considerable amount when spread over the many years that a well-constructed frame will give service. If, however, it is going to be a rough frame, not painted, and left out in the open when not in use, it would be better to use VDL.

When making a single floor frame one looks for as large a space as possible. The width depends upon the size and type of truck to be used, but should not exceed 9ft., for over that one may meet with complications in reference to traffic. The length of the frame should not exceed double the distance from the rear axle line to the back of the cab.

The floor frame may be made of 3in. x 2in. on edge, and if the tray of the truck is flat it may be placed lengthways unless it is intended to extend the floor more than 15in. beyond the truck tray. Where side rails are fitted on the tray and it is not desired to extend the frame more than 18in. behind the back end of the truck tray, the floor slats may be mounted straight across and the floor frame need only consist of three timbers 2in. wide and the depth of the side rail on the tray. These timbers to run the full length of the tray and be evenly spaced. The slats for the floor should be 2in. x $\frac{1}{2}$ in., and when nailing on may be spaced with a matchbox on edge. It is a good plan to run the plane along the top edges to prevent the sheep hoofs from splintering the edges.

TRANSPORTATION OF SHEEP
SINGLE FLOOR FRAME FOR MOTOR TRUCK

The side rails should be of 2in. x 2in., and if the slats are mounted across the tray, they should be screwed to the side rails with 2in. No. 10 screws, and to finish properly a piece of 1in. x 3/16th in. iron should be bolted along the bottom. Bolt the complete frame to the lorry tray with two or four 3/4in. bolts.

Next it will be necessary to have eyes for the upright standards for the sides and ends. These can be simply and effectively made by taking a piece of 2in. x 1/2in. mild steel and curling one end, and fixing with two bolts 2 1/2in. x 3/4in. The upright standards to be made of 1 1/2in. x 5/16th in. or 3/4in. The end should be rounded down to about 3/4in. to fit through the eyes and left long enough to drill a small hole at the bottom for a piece of wire or cotter pin. A better job is to cut a thread and fit a 3/4in. nut. On a frame 10ft. long three uprights should be sufficient, but for longer frames four are necessary, 9ft. wide front and back need three, for less than 7ft. two are sufficient.

The bottom board for the side hurdles is made of at least 6in. x 3/4in., to keep the sheep from putting their legs through the frame. The top board should be full 1in. x 4in. The four remaining boards should be 3in. x 3/4in., spaced with approximately 3in. between. These should be bolted to the uprights with 5/16th in. bolts. This will give a total frame height of 37in. If one is prepared to use a tarpaulin over the top, one of the centre boards can be eliminated, and thus bring the height down to 31in.

DIVISIONS AND DOORS.

The yard should be divided across the middle first of all, and then each of the two yards should be divided lengthways, making four yards in all. These divisions may be made of 4in. x 3/4in. for the top and bottom rails and 3in. x 3/4in. between. All these divisions should be securely strutted, as should also be the sides and end hurdles. The divisions are held in place by fixing plain eyes of 1in. x 3/4in. mild steel top and bottom, and held together by a 3/4in. pin. The corners are held the same way, only the bottom eye should be fixed just under half-way up in the corners.

The most suitable place to fit the doors is the centre of the left side. This allows one to drive straight in beside the unloading ramp at the Abattoirs. They can be constructed between the two centre standards, and each door should have an opening of not less than 1ft. 10ins. and not more than 2ft. 6ins. When loading, the pins from the centre division and the front and back division are pulled out, allowing the front and back divisions to be swung over to the gates. The right side yards are then loaded first, the divisions closed, and then the left yard may be filled.

The most effective and least obstructive door is the sliding type. It is simple to construct, cannot fall off, and may be opened anywhere beside the ramp. The middle boards only are cut out of the side hurdle, the top and bottom boards remaining. The upright, inside and out on that end of the gate which meets the other gate, is left extending over and below the two remaining boards in the side hurdle, which then acts as a guide for the doors. Make the doors of 2in. x 3/4in.; do not fit them tight. One strap around the middle will keep the two doors closed. The bottom rail of the door should rest on the bottom rail of the hurdle and the top one should be 3in. below the top rail, and the others evenly spaced between the boards of the side hurdles.

When making a double-decker, the main floor should be 7ft. 6in. wide and again should not be longer than twice the distance from the rear axle line to the rear of cab. If possible, it is preferable to put the slats across the tray, more particularly on a double-decker, as height is one of the chief considerations, and slats across give the lowest loading position.

The lower deck should have a total height clearance of 22in. With the aforementioned width, viz., 7ft. 6in., and the yard divided lengthways, will give each inside yard an inside width of 3ft. 7in. That is the correct width for three grown sheep or four lambs, if it is desirable to tie them down. The 22in. height gives ample head clearance for a sheep sitting down, and even if they are not tied down, immediately they find they cannot stand, they will go down in their natural position.

PLAN

SIDE ELEVATION

BACK ELEVATION

TRANSPORTATION OF SHEEP DOUBLE DECKER FRAME FOR MOTOR TRUCK

For the sides, the bottom board should again be 6in. x $\frac{1}{2}$ in., placed on top of the side rail, which is 2in. x 2in. Two more boards—3in. x $\frac{1}{2}$ in. given 3in. space—completes the side for the lower deck, leaving 2in. opening under bottom of second floor.

The rests for the second floor are made of angle iron $1\frac{1}{2}$ in. x $\frac{1}{2}$ in. running along each side hurdle and on each side of the middle hurdle. These angles should be securely bolted to the side-members with $\frac{1}{2}$ in. bolts, the top of angle being 22in. from the top of the lower floor.

The cross pieces for the top floor should be 2in. x 2in., and the slats placed lengthways. Each side floor should be made in two parts to facilitate fixing and removing for back loading, &c. After the floor is constructed, 24-gauge galvanized iron should be fixed from the top of inside slat down around the bottom to outside edge of cross piece. This iron should also be brought up to the top of slats in front of each section of floor, so that the urine will drain to the sides and not run forward with the natural tilt of the lorry and be blown back over the sheep.

To continue the timbering of the sides, the first board on the level of the second floor should be a 6in. board, with three more 3in. x $\frac{1}{2}$ in. spaced 3in. apart. This gives a total clearance on the second floor of 24in. This extra 2in. allows for the use of a tarpaulin cover, which is necessary to prevent the sheep jumping out. It is preferable to make a removable piece on the centre division to hold the tarpaulin up in the centre for better draining of water and better ventilation for the stock on top.

Gates.—In a double-decker of this sort, it is more difficult to fit gates in the side, but if a trailer is to be used, this will help considerably when loading and unloading. For solo work, however, the most suitable place is in the back of frame.

Whilst assembling the frame, have a tin of paint handy and put a little paint between all joints. In commercial practice of to-day that sort of thing is not done, one reason probably being that prices are cut to the bone; nevertheless, it was an old trade practice and one well worth while. After the frame is completed, it should receive at least two coats of first-quality paint in some suitable color, such as red or dark green.

In a frame of this sort a maximum loading space is obtained without excessive width or height, and a full load can be carried without side sway. The total height only amounts to 4ft. 1in.

The tying-down method of transport was evolved by Sir Edward Mitchell, of Victoria, and particulars of it appeared in the *Stock and Station Journal* some years ago. Briefly, it is done as follows:—The yard must be from 3ft. 6in. to 3ft. 9in. wide. Across the front is laid a bolster of some kind. I used a round bag filled with chaff about 1ft. to 15in. in diameter. Three sheep are then put down side by side, with their chests against the bolster. The legs are put under the sheep—as a sheep lying in the field. A canvas strap 18in. wide, with a leather strap in each corner, is then fastened to the hurdle on each side and stretched across the sheep's back. The sheep rises back end first. When it discovers that it cannot get its back up it will sit down again. The next three are then put down with their chests up against the rumps of the front sheep. In a frame 12ft. 6in. long one can get five lots of three medium-sized sheep. When loading lambs, four are placed across, so that, roughly speaking, a double-decker 7ft. 6in. x 12ft. 6in. will give a carrying capacity of from 48 large-framed fat wethers to 80 sucker lambs. A frame measuring 7ft. x 10ft. on a 1-ton truck will carry 36 large sheep to 46 sucker lambs.

The one serious objection to this method is the time taken to load. It takes two men on the lorry with one other loading, at least an hour to load 60 sheep. However, they carry exceedingly well, and give no bother on the road. I have personally taken lambs to the freezers this way, and I have never had more than one reject in a load; that is, from load bruises, and not counting hand grips in the wool.

As time went on we discontinued tying down. We merely load the lambs in the frame, and when they find they cannot stand comfortably, they sit of their own accord.

One has to sacrifice some of his load this way, so that instead of carrying approximately 80 lambs, one may have to reduce to about 65. I have now both a single-floor and a double-decker in use, and I am quite convinced that the low clearance double-decker is the better, and also the more humane method of transport.

LOADING.

When loading sheep, and lambs in particular, handle them carefully. Dogs that bite should be chained up or muzzled whilst yarding sheep for loading, and the sheep should be taken very quietly to prevent them rushing about the yards, where they might also bruise. There is, however, a phase in the loading process which few people seem to bother about—how to raise the sheep and lambs to the necessary height. On some farms, one finds well-constructed ramps, or a raised yard, say, 3ft. 6in. to 4ft. high, with a sloping yard up to it. Such a yard should be approximately 10ft. x 10ft., and the sloping yard should be the same width, as it may have a rise of about 1 in 3½. Cement concrete is the best method of construction. Another point of importance about the elevated yard is the exit gate. This should be placed in such a position that the lorry has a clear drive past. The gate itself should be made to slide sideways, or drop between two guides, and be suspended by a rope over a pulley, with counterweights to balance.

Such a method of loading will immediately commend itself. Unfortunately it is not practical for the small lamb raiser, because it is rather expensive, and for the larger breeder it is not portable. Then, from the point of view of the driver of the lorry, the question of loading becomes very important, and also a very vexed one. We have tried making light loading races, varying from 8ft. to 16ft. in length, but so far have met with no success, as the sheep try to jump over the side or baulk, and then the handling necessary is worse than lifting straight up. In a double-decker the height to the second floor is considerable. Another method tried was to put a platform across the corner of the yard on top of the fence, and then put the sheep up there, and from there to the lorry. Then, again, some yards have not got a fence substantial enough to carry such a platform, and which in itself is not a very convenient thing to carry.

An elevator made to load sheep similar to one used for loading wheat seems somewhat far fetched; but if it could be worked it is what we are looking for. So far we have come to a deadlock in this business, and still have to revert to the old style of handing up.

There, again, various methods may be adopted, but the way we usually load where no elevated yard is available is for one to catch the sheep, and two others join hands and lift under the brisket, while taking hold of the back legs below the hock, with the free hand, and the one who caught the sheep assists with open hands at the back. The sheep is then raised, and its front legs put on the floor and then gently pushed forward until its hind feet can be put on the floor as well. There is always the danger that if the sheep struggles violently it will drag its back legs over the edge and bruise from the stifle joint down.

DRIVING.

A bad driver can do nearly as much damage to lambs as those who load them. Always attempt to keep the lorry on an even road, and not drive on the camber of the road; this tends to throw the sheep over one side. It is also well to drive as straight as possible; swerving also tends to throw sheep from one side to the other. This applies more particularly when sheep are standing. Quick starts and sudden stops are also bad. The lorry should be driven at a speed in accordance with the road conditions. On a good bitumen road a careful driver might easily drive 40 miles per hour and give his sheep a good ride; and on the other hand, a 10 miles per hour speed may be much too fast on other roads, particularly where one has to drive in deep wheel tracks or a deep track cut in sand where there is a good deal of side

sway. It is under these conditions that large single-floor or high double-deckers are difficult to handle, and knock the sheep about much more than a low clearance double-decker does.

Drive with consideration for other people on the road. Remember you have a big vehicle on the road, perhaps not quite as bad as a trolley load of hay, but much faster. So far the traffic laws have not interfered with drivers with sheep frames, and I am inclined to think that while drivers exercise every care, and do not make themselves a nuisance, no action will be taken. If, on the other hand, they do make a menace of the vehicles under their control, something that we will not like may be done, and the innocent will have to suffer along with the guilty. Anything that can be done to truck sheep, and more particularly lambs, speedily and with less damage, will go a long way to solve the very vexed question of reject carcasses caused through transport.

BULK HANDLING OF WHEAT.

[By M. D. WRIGHT, Boors' Plains.]

It is not easy to estimate how long it will take the wheat industry of Australia to recover from the harassing period of depression and world's low prices which it has encountered in the past two seasons. Periodically, hopes of obtaining increased prices for cereals are raised by rumors of a bounty or some form of Government assistance. Recently, it was hoped that some agreement would be arrived at in connection with the limitation of exports at the World's Economic Conference in London. It was felt that wheatgrowers were entitled to some arrangement whereby the prices of wheat could be increased, but unfortunately that matter is still unsettled.

If previous periods of depression can be taken as a guide, wheatgrowers may be confronted by the prospects of slowly improving prices for their wheat, once the accumulated world's stocks are reduced. The position depends mainly on the extent of the Northern Hemisphere crops this year. So far, both the United States and Canada show a material decrease compared with last year. For Australia to discontinue growing wheat—particularly in surest districts—would be a calamity, mainly because wheatgrowing in Australia has proved its national worth. In other periods of commercial and financial depression, it has been one of the nerve centres, from which financial experts have extracted a ray of hope in solving the problems that confronted them. South Australian wheatgrowers have shown the way in the past for making wheatgrowing profitable, by adopting proper fallowing and advanced cultivation methods. The acknowledged fact that the average yield has greatly improved, proves beyond doubt the great national value of advanced methods. In certain parts of New South Wales it is an acknowledged fact that South Australian farmers introduced farming methods which were responsible for those centres producing the large quantity and high acreage average that they are doing to-day. Farmers realise more than ever to-day the necessity for reducing the cost of production; every farmer in some way has endeavored to reduce his costs; in some cases large amounts have been saved, in others the difference is barely noticeable, but in the majority of cases the trend has been to reduce costs of production. Therefore, farmers are endeavoring to produce their products at the lowest possible cost. On the other hand, the value of products is lessened because of handling charges, rail, transport, and shipping costs; therefore, it is equally essential that these charges should be reduced to meet the low prices offering for wheat and to give an opportunity of making a living—if not a small profit—from our holdings. In bulk handling there are possibilities whereby these outside costs may be eventually reduced to a minimum.

All those who have interested themselves in this subject are aware that the S.A. Farmers' Co-operative Union and the S.A. Co-operative Wheat Pools Limited have carefully investigated every phase of bulk handling in Canada and Australia, as well as methods of handling wheat in countries where Australian wheat is exported. The Canadian system can be ruled out, climatic conditions being totally different in Canada

and Australia. Australian wheat is sold under one grade, Canadian is sold under many grades, and care has to be taken on account of the greater danger of wheat heating in Canada.

BULK HANDLING IN NEW SOUTH WALES.

The system adopted in New South Wales at its inception was largely on the lines of that of Canada, more particularly with regard to the construction of silos, which were far too costly, and meant high capital cost, on which interest had to be paid as well as some amount allowed for depreciation. Latterly, however, the management of the New South Wales silos has arranged a country silo which can be erected for about £7,000 fully equipped; 14 units holding 90,000bush. is its capacity. In South Australia there are 300 receiving stations where 90,000bush. or more are delivered. If provision is to be made for receiving two-thirds of the wheat, the capital cost would be too great; therefore, some less expensive method of storage is desirable. In this connection, the Westralian Farmers' Co-operative Company has been successfully experimenting during the past two years with bulk sheds similar to the present wheat sheds at railway stations in South Australia. A damp-proof floor is provided, the walls of the shed are of double corrugated galvanized iron, curved to add additional strength, with sufficient strong upright wooden posts to keep the iron in position. The walls of this container are 10ft., and a further 4ft. or 5ft. single iron high, and are well stayed to prevent the sides or ends being forced out, the structure being roofed in the ordinary way.

The method of placing wheat into these sheds is by a portable elevator bucket or slat type, on which is provided a bin, into which the wheat is tipped by the farmer. The wheat is elevated to the height of 30ft., from whence it will gravitate to the position in the shed required or into railway trucks, if so desired.

The method of emptying the shed is by the same elevator, provision having been made in the walls of the shed for the wheat to run out in the bin of the elevator; when it ceases to run out the elevator can be put inside the shed and moved up to the wheat required, a Clark shovel being used to assist in filling the elevator.

The Westralian Farmers Limited system is efficient, and may be described as a collective storage of wheat at country railway sidings, with facilities for quick movement to shipping points. This State has certain disabilities in that it has six main shipping points—three with long jetties; but, on the other hand, its railway system will permit the expeditious despatch of grain from the country to seaboard.

The great advantage of the portable elevator is that it can be moved up to the wheat when loading railway trucks from the shed; the power is supplied to these 30ft. elevators by 4½ h.p. engines; crude oil would appear the most economical fuel. One man only is required to attend the elevators when receiving wheat from the farmer; the capacity of the elevator is 1 ton or 37bush. per minute, 700 bags per hour; cost of elevator £300. No wheat lumpers are required for putting wheat into stack as at present.

Quite a large number of the present railway trucks are quite suitable for conveying wheat in bulk. A ridge pole along the centre of the truck so that the wheat could be covered in case of rain is all that is required. Railway trucks will carry as much bulk wheat as bagged. Very little storage capacity will be required at sea ports, the idea being to load wheat direct from truck into overseas vessels and eliminate double handling as far as possible.

As regards loading from trucks into ships: at present the Stevedoring Company finds all plant required, and is agreeable to provide plant to load from truck to ship at no additional cost. One thousand tons of bulk wheat must be loaded per day, whereas only 500 tons of bagged are required. Overseas freight is 2s. 6d. per ton less on bulk wheat than bagged; the price obtained for bagged wheat a few years ago was about 1½d. per bushel better, but to-day the difference in freight more than pays the difference in price received.

When comparing the respective cost per bushel for handling wheat under the present bag system, and under the proposed bulk system, the following items must be carefully considered:—

(1) Cost of bags; (2) handling charges at country stations; (3) rent of sites, provision for dunnage and roofing material at country stations; (4) rail charges; (5) seaboard charges, including stevedoring charges; (6) despatch money; (7) ocean freight; (8) value of bagged and bulk wheat; (9) sundry other handling charges, including administrative charges.

Throughout these considerations, conservative figures are taken of the bulk benefits in contrast to those of bagged benefits. After a close analysis of these factors it is seen that the bulk system shows an advantage of 2½d. per bushel, made up as follows:—

Estimated savings under bulk handling:—

Cost of bags at 9s. per dozen	d.	3
Country agent's commission	1½	
Dunnage, roofing, curtaining, re-conditioning, loss by mice, weather, etc., rent and depreciation of sheds	½	
Seaboard charges	¼	
Ocean freight	¼	
Slinging and superintending discharge	¼	
Sewing bags and twine	½	
	—	6½
Deduct—		
Value of bags sold as wheat	½	
Bags required to deliver wheat (¼ usual number for two years) . .	¼	
Difference in value bagged and bulk wheat	¼	
Buying agent's commission	¼	
Operating costs	¼	
Sinking fund to cover interest and capital depreciation, 10 per cent.	1½	
	—	3½
Net saving		2½d.

MODES OF DELIVERING WHEAT.

From inquiries made it is found that in Western Australia three methods are commonly used. A farmer with a motor truck stands the bags upright on same, leaning them together and against the cabin without sewing them up. Others have a bin on their waggon or trolley and load the wheat with the ordinary Perkins loader, having fitted plain galvanised iron where the bag is placed, the horse pulls the bag up in the usual way, and the bag empties itself into the bin. Other farmers fix the top of their bags with two wire skewers which can be easily removed prior to tipping. The best proof of the popularity of the bulk system compared with bagged is that farmers do not mind carting their wheat an additional 10 or 15 miles to avail themselves of the bulk methods.

One important factor in connection with bulk handling is the saving of time. All are aware of the time it takes to sew a waggon or lorry load of wheat. Compare, then, this method with that of the bulk system, where a boy can fasten a load up in an hour with skewers made from fencing wire. Under this system that laborious and weary job of ramming, dumping, and sewing of bags can be done away with. The saving of time again plays its part when the wheat is delivered. A statement in support of this assertion comes from Benjabbering, Western Australia. There was no long waiting at the siding as with bagged wheat. The waggon was weighed in, unloaded, and weighed out. In 15 minutes the job was finished. Though nearly twice as much wheat was handled at Benjabbering last harvest than ever before, no team was held up. Another report in reference to the saving of time comes from a farmer who has had some experience with bulk handling methods and who states that he delivered 12,400bush. in the season 1931-32 with a 4-ton tabletop trolley with a bin built on it capable of holding 140bush. The time taken to unload the 140bush. was seven to eight minutes. He further states that he is considerably over £100 in pocket, and

claims that bulk handling is the only genuine effort that has been made to decrease the cost of production, and so keep the farmer on the land. Not only does the farmer save time with this system, but the merchant does also. Bulked wheat is easier to truck and easier to load on ships. Five hundred tons of bagged wheat are required a day, whereas 1,000 tons of bulk are required. In May last a vessel commenced loading bulk wheat at White Bay—the New South Wales terminal—at 8 a.m. At 10 p.m. it was completely loaded with 7,500 tons, or 535 tons an hour. The same vessel when loaded with bagged wheat at Port Lincoln on a previous trip required 16 days. As pointed out earlier, wharfage charges, harbor dues, and stevedoring fees are all deducted from the price before it is quoted to the farmer. Therefore, the New South Wales seller was 15 days' worth of charges better off than Port Lincoln farmers who still labor under bagged wheat methods. Strong support for bulk handling of wheat was expressed by Mr. H. W. Lyons, M.P., during his speech on the Address-in-Reply in the Assembly. He stated that "there is no doubt that bulk handling would be beneficial to the primary producers of South Australia." Mr. Lyons, before making this statement, had gone into the matter of bulk handling with the Director of Agriculture in Western Australia (Mr. G. L. Sutton). In his address to the Assembly he pointed out the advantages to be gained by the farmer under this system, the saving of time and expense in shipping, and the lower freight rates.

There is one point to bear in mind, and one that Mr. Lyons pointed out in his speech, and that is:—"Almost all ports in Britain and on the Continent are equipped to deal with wheat in bulk. This proposed system of dealing with our wheat is not a new idea; it is one that has a solid foundation in many parts, one that has been proved to be efficient and a success. Certain firms in the other States, and also one in South Australia, have made trial shipments of bulk handling by having the bags cut open after delivery on the vessels, with the result that even after handling, &c., a profit was made. Firms do not take those steps unless a profit is to be made. It must be profitable for them to ship in bulk, otherwise they would not do it. If we instal this system we shall keep within our own country the enormous sums sent away every year for cornsacks."

The average quality of our wheat will be improved by adopting this system of handling; the improvement of our quality is necessary if we wish to maintain our overseas markets.

Bulk handling holds unlimited possibilities for us as wheat-growers. We are passing through a period of low prices and depression, and the future holds no ray of light for an improvement. Therefore, it behoves us to grasp at every opportunity that presents itself to lower costs of production. In bulk handling there are possibilities of reducing costs that will never present themselves under the present system. As farmers, as a community, as a State, we should view this proposed system with unbiased minds. The financial stability of the country depends largely on the primary producers. As individuals we have a responsibility to our State, and in a question such as this our thoughts should be national and unbiased, so that a fair and honest decision may be arrived at.

PIGFEEDING.

[By A. F. ROBERTSON, Wauralte.]

The main object sought in the feeding of pigs is to produce a suitable carcass (if for market requirements) in as short a time as possible with a minimum of food cost. There are several factors which contribute to this end that must be taken into account. These are:—(a) The type of pig required for present-day market requirements; and, (b) the best type suited for breeding purposes.

The class of pig best suited to our market is one that does not carry an undue proportion of fat to lean; the overfat pig is undesirable and difficult to sell profitably. Then, again, the undeveloped animal is also unprofitable. It should, therefore, be

the aim of the pigraiser to produce a line that makes a ready sale and a quick turnover in as short time as is possible, consistent with trade requirements. In order to obtain the desired results he must feed correctly and with the understanding, right from the beginning, that it is not profitable to stunt the young pigs if good baconers are required later on, say, when the pigs are from 5½ to 6 months of age.

As with all growing animals, the pig requires certain constituents in its food to maintain its daily needs to develop flesh and bone, &c. Experiments have shown that the pig requires a definite proportion of protein to make good growth and lean meat, and this protein may be obtained from many sources. Farmers who have plenty of separated milk only need cereals, such as barley meal, middlings, or pollard, to obtain best results. Where a limited supply of separated milk is to be had, the young pigs should have the preference. The man with any large number of pigs will find it will pay him to mix his own meal. The best method of efficiency and management is the number of pounds of meal to feed to 1lb. of live weight in the pig. In order to obtain this result it is necessary to work on the basis of about 4lbs. of meal to give 1lb. increase. Good feeders know that this could be obtained and even bettered. The balanced ration will give a better grade carcass with less fat.

Scientific feeding carried out systematically will pay—unless market prices are very low. The man who feeds systematically will always produce a better quality animal than the man who feeds haphazardly. The better way may not always be the cheaper, and the amount of profit shown will depend upon market rates. Feeding a balanced ration is an all-important matter in order to produce the very best type of animal.

It is difficult to find a suitable situation of really ideal conditions, as it is always necessary to supplement pasture grazing with some method of hand feeding. In all the agricultural areas of this State there is always to be had an ample supply of cereals, which are the staple food of the pig. Cereals are not sufficient by themselves, whether fed whole, crushed, or cooked, as they are lacking in certain minerals. It is, therefore, necessary that the proportion of mineral needed should be added.

It should always be borne in mind that the young weaned pig will require much more protein than that of bacon weight, which means that at suitable periods during the animal's development—say, about every six weeks—a variation of the mixture is necessary, gradually reducing the protein and mineral mixture to suit the requirements of the pig.

As there is nearly always a certain amount of inferior quality grain on many farms, the feeding of this to pigs and farm stock in general may possibly be turned to profitable account, although best results are obtained from best quality grain.

SHEEP VERSUS WHEAT ON OUR POORER COUNTRY.

[By M. NEWBOLD, Wauralteë.]

My intention with this paper is to bring under your notice for consideration whether it would not be better to increase our sheep flocks and grow less wheat where we are now growing wheat on a considerable amount of our poorer limestone country near the coast and within two and three miles of it on the western side of Yorke Peninsula more particularly. My remarks are not intended to apply to our better class country.

There is very little, if anything, but hard work in wheat growing at present, even where yields are up around the 20bush. to 25bush. per acre mark, and consequently much less so where the yield is round about 10bush. to 12bush. per acre. A rather remarkable thing about this poorer country is that with an occasional dressing of superphosphate when cropped it grows wonderful feed.

I have taken as a basis of calculation 500 acres of country, of which 300 acres are cropped each year, 200 acres of wheat on fallow and 100 acres of barley on stubble. The following are the main items in connection with both sides.

GRAIN.

	£	s.	d.
200 acres wheat at 12bush. = 2,400bush at 2s. bush.	240	0	0

Carting of produce to market has not been reckoned in, but this would also result in favor of the sheep. On paper the sheep look to be the thing at the present time, taking wool at 1s. lb., which is a fair price. Even with wool at a lower figure it looks as though sheep are the better proposition.

If a man has no sheep and has to buy, it would be wisest, at present, to buy a few good quality young ewes and gradually breed up a flock. With the man who has a fair flock of sheep it would not be a very hard matter to increase his flock to cope with the situation.

SOUTH-EASTERN CONFERENCE, WOLSELEY, MARCH 21st, 1934.

SOMETHING ABOUT MALTING BARLEY.

[By H. BOND, Tatiara.]

After a farmer has sown enough oats to meet his requirements, and as much wheat as he can afford to, it is a fair investment to put in a patch of malting barley. Barley has not been widely grown in this district, but at the present time it is as good a proposition as anything else.

“Malting” is very closely associated with the word melting, and in this case means soaking barley in water until it grows, when the starch in the grain becomes softened and later is converted into a sugary matter. Malt is the broad term covering this product, which is principally used in beer, whisky, yeast, vinegar, gin, malt extract, and several compounds used in baking.

Barley can be most economically grown on the loam and the light and sandy soils of this district. The rich, heavy land will also grow it well, but there is more risk in getting it away to a good start. Barley does well on wheat stubble—a deficiency of nitrogen in the land for wheat being an asset to barley.

The best time to commence seeding is from the middle of June to the end of July. Sowing may also be continued during August, but the chances of getting malting quality are lessened, although the farmer may reap many bags per acre.

It is very difficult to distinguish the different qualities in malting barley. Mr. A. G. Barrett, of Barrett Bros., maltsters, says:—"It is only after long experience that a maltster can select his lines; that it is impossible to explain how one recognises type; and no chemical formula has yet been devised which will replace visual judgment." With that in mind, it is hardly worth while for a farmer to become an authority on the various grades of barley, although there are a few principles he can follow which may help him evade loss. It is unwise to thresh barley too thoroughly; it is better to leave some beards on than to knock them all off. Hard threshing results in broken jackets, and the barley either rots or moulds during malting, thereby spoiling the product. More than 5 per cent. of damaged grain will disqualify a good line, and this means up to 6d. a bushel loss to the grower.

Barley in this district is at its best when used as a utility crop. It is at least six or seven weeks shorter-lived than wheat or oats. It is not advisable to sow barley too thickly. There is plenty of grain in 40lbs. of good seed to grow a 30bush. crop. Many experts believe that few crops over 25bush. to the acre produce the best grain.

So far I have always believed that Prior barley was the best for local conditions, but last season I sowed a bag of Californian Cape Malting. It has a six-row head and is the type with which the United States captured the British trade. Four acres reaped 50 bags. Samples were sent to several maltsters, who informed their agents that it was high-class malting, and to buy all they could of it. This barley was grown on very light land, and will, when sown on the good loam of the district, produce excellent yields. The present Prior is good and reliable and farmers should not pay extravagant prices for any new varieties.

Pickle with a bluestone solution a couple of months before sowing. Apply as much superphosphate as finances will permit—anything up to a bag to the acre—particularly if on light land. And, last but not least, have the ground clean when the barley is sown.

HOW I FALLOW.

[By G. D. BUTLER, Wolseley.]

This paper embodies the results of observations, investigations, and experiments of recent years, which have led me to adopt the system hereinafter outlined. Those parts of the Wimmera that have clayey soils are blessed with a milder winter, and farmers do not run so many sheep. In other countries clay soils are universally condemned as hardly fit for farming, and commended only for grazing. Indeed, were it not for the long, dry summer, which aerates and divides the soil by cracking, successful farming under any system would be a very doubtful undertaking.

I fallow two paddocks: No. 1 on wheat stubble; No. 2 has been under grass for two, three, or four years. Paddock No. 1: The burning of this stubble is left as late as possible. Should good March or April rains fall, these ensure a growth of self-sown wheat and weeds. The fire kills these off, thus saving a cultivation. This paddock is not touched until about the middle or end of May. When the ground is too wet to sow wheat or oats, the land is worked with a scarifier lin. to 1½ in. deep. This job is completed by June 21st; if left later the ground becomes too tough to be scarified. All dates are given as a general guide; in practice, the condition of the ground and the weather is taken into consideration, and not the calendar. The job

is intermittent, for until all seeding is finished, it is only carried on with when seeding is impossible or inadvisable. In all my paddocks there is a small area of wet and/or shallow soil, which does not respond well to the scarifier. This area, together with any of the better land which was not scarified early enough, is left for a few weeks and then ploughed as shallow as possible. The object in waiting is to permit a growth of grass, the roots of which bind a sod that the plough can turn over.

The ploughed part is harrowed twice as circumstances permit, but the other is left until the middle of August. Weeds are kept down with sheep, but the sheep are not allowed to pug the soil. Between August 21st and September 7th I again scarify the scarified fallow, going just a little deeper. It is particularly important to get this second working done at this time.

The whole paddock is subsequently worked, as rainfall and other circumstances permit, with the scarifier until Christmas, with the combine afterwards.

Thistles, &c., are kept down by sheep, knife-bar, and hand-hoe. The sheep have access to the fallow all through summer and they walk over it every day. They find next to nothing to eat, but their walking about fills in the cracks and is as good as a working.

As soon as the first paddock is finished, No. 2 is worked, using a skeleton mould-board plough fitted with L.P.W. shares, ploughing about 2in. deep. At this depth the ordinary P. or L.P. share will neither completely cut nor invert the 8in. to 8½in. furrow slice, but the extra width of the L.P.W. does the trick. This combination is not the best that can be achieved. A set plough, cutting narrower furrows, say, 6in., and with a correspondingly shorter lead, may eventually be found more suitable for our soils.

Except for small areas of very dirty, black ground I have discarded the practice of summer fallowing, because the early winter is usually too wet to give it the necessary working; the few fine days in June are needed to finish off seeding. I endeavor

TOP SPECIAL SUPER (45%)

“TOP” IT, AND PROFIT.

The Adelaide Chemical & Fertilizer Co., Ltd.

to finish paddock No. 2 by the end of July; early August is often the best time for harrowing. I harrow at least twice, as and when I can. The first harrowing, if done at right angles to the ploughing, turns back too much of the unrotted furrow slice; harrowing with the ploughing has too little effect. Harrowing at an angle of 25 to 30 degrees from the direction of ploughing gives a maximum of break with a minimum of undesirable turnover. The second harrowing is done at right angles to the first. The direction of the third stroke—if done—depends on circumstances prevailing at the time. I use medium weight harrows, weighted when necessary with an old post.

One of the advantages of shallow ploughing is that harrowing can be done effectively much earlier in the season than with deeper ploughing, thus getting a fairly fine division of the surface soil while the underlayers are still wet enough to be consolidated by the tramping of the horses. This finer division encourages germination of weed seeds and weeds are easier to kill in September and October than they are in May and June. This fallow is usually scarified about 1½ in. deep as soon as possible after finishing the second working of No. 1. The repeated harrowing and late rains set the fallow too tight for it to be turned up by any implement other than the scarifier, and because it will shear through the unbroken furrow slice that a combine would simply turn over or jump over. In some years it is advisable to use the combine first, but on those occasions it was necessary to scarify it a month later. From now on this paddock receives the same treatment as No. 1, and is worked as circumstances permit.

No one reading the foregoing can help noticing the importance of the scarifier. Up-to-date and payable farming is impossible on unlevelled ground, and it is most essential to rid the land of stumps to a depth of 4 in. to 5 in. Only set harrows are of any use, and they are only useful when the tines are sharp and straight; a few stumps will soon reduce the effectiveness of a set of harrows by 50 per cent.

My method of de-stumping is simple. During what is expected to be the last spring working I carry a number of wooden pegs. One of these is driven in near every stump that the machine bumps over. Later, the dirt is grubbed from around these stumps to a depth of 4 in. or 5 in., and when the soil is very dry the stump is burnt out with the aid of spoiled chaff or dry stable manure. Hundreds of old bull-oak stumps did not need a fire; they were split and levered out with a crowbar.

I am not in favor of working the land after harvest rains; if the fallow is in good order I do not touch it. If the cultivating season has not been good, and clods are prevalent, they can be broken down with the harrows upside down and weighted, used preferably after a light rain. Clods serve no useful purpose, and are full of weed seeds that do not germinate until it is too late to destroy them.

A fine shallow mulch is better than a deeper and cloddier mulch, for after the frequent heavy May-June rains it dries out to a workable condition much quicker than the latter. Indeed, if the latter becomes waterlogged it remains so until spring, unless the winter is dry. My best crops of recent years were grown on fallow that was set so tight at seeding time that it became necessary to use a rigid-tine combine.

No doubt this method may seem difficult and complicated to those used to the older and simpler method, but examination will show that it is really much easier to accomplish. More important, the yields are better than could be obtained under the old system without a lot more effort. All the earlier workings are easier and quicker, and the soil is more often in a workable condition.

The shallow ploughing of No. 2 is especially easy on the team, just at the time when it is hardly fit for a heavy job, and there is no need for the spiked log.

I remove several tines from the scarifier for the earlier breaks; indeed, if the machine was the right load for the team in winter, it stands to reason that it is too light and small for the earlier spring workings. Fixed scrapers on the rear wheels are indispensable.

MID-NORTH CONFERENCE, LAURA, MARCH 14th, 1934.**BUSH FIRE LEGISLATION.**

[R. J. ROSE, Laura.]

Prior to the Bush Fires Act, 1913, being assented to, district councils under the provision of section 234, District Councils Act, 1887, had conferred upon them powers to deal with outbreaks of fires within their respective areas. This clause was, however, repealed, and there was enacted in lieu of this The Bush Fires Act of 1913, followed by amending Acts in 1916, 1926, and two in 1931.

The Northern Fire-fighting Association in 1916 submitted to the then Minister of Agriculture a series of recommendations for amending and new legislation, practically the whole of which were incorporated in the 1916 Act; also at a later date recommendations were incorporated in the 1926 and 1931 Acts.

Consolidating Act.—The legislation now in force is contained in the Bush Fires Act of 1933, assented to on December 7th of that year, and the specific object of this paper is to submit in a concise form a summary of existing legislation. In addition to the request that a Consolidating Act should be passed, a deputation appointed by a Conference of Fire-fighting Associations which met at Clare in March, 1933, which consisted of Messrs. G. H. C. Warren (President Barossa Association), Norman Brookman (Hills Association), and R. J. Rose (Hon. Secretary of Northern Association), waited upon the Minister of Agriculture (Hon. A. P. Blesing), and submitted a series of recommendations for amending and additional legislation, these requests being supported by the Stockowners' Association of South Australia and several Parliamentarians representing districts in which Fire-fighting and Fire-prevention Associations were functioning.

In delivering judgment at a County Magistrate's Court in a case where a landowner was charged with a breach of the Bush Fires Act, the presiding Magistrate said:—"It is the responsibility of every landowner to make himself familiar with the Acts of Parliament which affect him," and to impart some information regarding legislation which affect every man on the land is the objective of this paper.

Bush Fires Act, 1933.—The Bush Fires Act of 1933 consists of 36 sections, its objective being designed in the preamble as "An Act to make better provision for the better control of Bush Fires and other Fires and for other purposes."

Scrub and Stubble Burning.—Sections 4 to 8 inclusive deal with stubble and scrub burning, and for the most part re-enact legislation formerly on the Statute Book of the State. Included in these sections are, however, some new provisions. Persons who intend to burn stubble, *i.e.*, "stubble, hay, straw, grass and herbage, whether alive or not alive, and whether standing or not standing," are now required to give notice to adjoining owners or occupiers not less than *six hours'* notice (former legislation required that not less than *twelve hours'* notice should be given). Notice now must, as aforesaid, be also given to the clerk of the council of the area in which the land is situated, or to the nearest fire-control officer. No stubble burning is to commence before *two o'clock* in the afternoon; former legislation permitted such fires to be lighted at *nine o'clock* in the forenoon. Scrub burning must not be commenced before *twelve noon*. Former legislation is re-enacted governing the clearing of space immediately adjoining, and the presence of at least four persons at the fire from the time it is lighted until thoroughly extinguished. Councils may under defined conditions burn off "stubble" in streets, roads, and reserves without complying with conditions that apply to ordinary stubble burning. Former legislation is also re-enacted for the burning of stubble in or on irrigation channels or lucerne fields. The Minister is empowered to grant permission to councils to alter the periods and the hours for burning, also distances.

Section 6 provides that with the consent of a Fire Control Officer a firerake may be used to burn stubble, provided that before the fire is lighted a space of 12ft. is cleared around the land or a space the width of 6ft. is ploughed.

No alteration of distances, however, shall be approved by the Minister unless the councils of all the areas adjoining such first-mentioned area agree to such alteration.

Since the Act was assented to the question has been raised as to the period that any of the above alterations shall remain in force. This has been submitted to the Minister for a ruling.

Sunday Fires, &c.—Fires for scrub, stubble, charcoal or lime burning must not be lighted on Sundays. Between October 1st and May 1st camp fires, &c., must not be lighted unless space the width of 12ft. has been previously cleared of all inflammable material.

Steam and Internal Combustion Engines.—Section 15 is new, providing that every stationary steam engine (other than a steam engine enclosed on four sides with non-inflammable material) must be placed so that there is a cleared space of a width of at least 12ft., and the same applies to stationary internal combustion engines.

Section 17 provides that all internal combustion engines used in harvesting operations must be fitted with an effective spark arrester; that when used the whole length of the area to be harvested must be ploughed or cleared of all inflammable material to a width of 12ft. If on such engines there is a water-spray of the knapsack pattern fully charged with water, ploughing or clearing to a width of 6ft. is all that is required.

Beekeepers and Smokers.—Beekeepers by the provision of section 16 are required, between the 31st day of October and the following 1st day of May, when taking honey with the aid of smokers or lights or maintaining a fire in a honey house, to have a space around the beehive, honey house, or apiary cleared to a width of 12ft., or a space ploughed to the width of 6ft.

Cigarettes and Cigars.—Section 19 fixes a penalty of not less than £2 nor more than £20 upon any person who between October 31st and 1st day of the following May, while being conveyed in any moving vehicle in any part of the State, outside a municipality or a town, throws out a lighted cigarette or cigar.

Clearing Roads.—Section 26 empowers councils to grant occupiers of land to clear roads of scrub for purpose of making firebreaks.

Inquests on Fires.—Section 27 is practically a copy of West Australian legislation, and provides that, except where a fire is confined to a building or other premises, an inquest on any fire shall be held, when a request in writing is made to the police officer in charge of the Police Station nearest to the fire, within three days of the outbreak by the owner of the area in which the fire occurred, or by any owner or occupier of property who suffered loss by reason of the fire.

Council May Expend Rates.—Section 28 empowers councils to spend rates in clearing roads of stubble and the purchase of fire-prevention apparatus, &c.

Fire Control Officers.—Since 1913 municipal and district councils have been empowered to appoint fire control officers, who are vested as far as practicable with all the duties and powers of the chief officer of Fire Brigades. In 1926, by an Amending Act, councils were empowered to increase the maximum number of such officers to 15. In 1931 further amendments were made to this phase of bush fires legislation, including the provision for the appointment of fire control officers, in areas not included in municipal or district council areas. In the 1933 Act additional legislation of an important character relating to fire control officers has been incorporated. Clause 2 of section 29 provides that if the Minister is satisfied that any council has not appointed fire control officers sufficient for its area, he may appoint officers for such area. Clause 7 of the same section confers upon gazetted fire control officers power to act as such in an adjacent area, if a fire occurs and no fire control officer

appointed for the area is present. Clause 9 of the same section provides that in addition to every forester and assistant forester employed in the Woods and Forest Department in the State, every foreman in charge of any Government forest shall, *ex officio*, be deemed to be a fire control officer.

Copies of the Bush Fires Act, 1933, may be obtained from the Government Printer, Adelaide; price 1s., plus postage 1d.

GROWING AND HARVESTING A LUCERNE CROP FOR SEED.

[H. K. MOORE, Jamestown.]

It is assumed that the lucerne, a good upright variety known as Broad-leaf Hunter River or Australian, has already been established in the field for several years, and the owner wishes to reserve some or the whole of it for seed.

Take all stock off the field during the last two weeks in August and September, to give the lucerne and other undergrowth a chance to grow sufficiently high to get a good clean cut with the mower. This ensures a good clean second growth, which is essential to get seed free from weeds.

In the Belalie district the second growth is fed off until the middle of December or a little later, according to season. Then take off all stock and allow the crop to grow; it should be in full flower by the end of January, and if nothing hinders it, should be ready to take off about the middle of March.

The best seed is obtained from comparatively thin stands of lucerne, the plants being further apart allows plenty of sunlight to penetrate around the leaves and flowers, giving it a better chance to mature good seed. A thick stand seldom produces much seed. In the early spring the lucerne flea does a lot of harm, but usually disappears after heavy grazing after the first cut and warm dry weather sets in.

“Dollman's Farmers' Friend”

The SCIENTIFIC WET AND DRY PICKLE

If frequent thunderstorms occur during summer it creates favorable conditions for the hatching of the boll worm, which does a lot of harm by eating off the flower of the lucerne plant, thus rendering it useless for seed.

This season practically all the lucerne in the district reserved for seed was spoiled and had to be fed off. Some stands have since grown and flowered and are setting fairly well, but the yields will be light on account of the dry spell and late ripening.

The seed should be left to ripen until most of the pods are dark-brown or nearly black in color. There will always be some green pods owing to late flowers. Harvest when the weather is warm and dry to ensure good threshing. The method of harvesting is similar to other grains; the stripper, harvester and header are used, with a few alterations to combs, sieves, &c. The header and harvester clean the seed in the one operation, but with the stripper it is dumped in heaps on tarpaulins and cleaned with the ordinary winnower or grader.

With the stripper care must be taken not to make a big heap, or leave it more than a few hours before cleaning or turning, because the green leaves and stems get very hot and soon ruin the seed. All seed—whether reaped by header, harvester, or stripper—should be thoroughly dry before it is bagged and put away, otherwise it will develop mould, which spoils its germinating powers.

After cleaning the seed there will be a quantity of unthreshed pods which contain a lot of good seed; these can be put through the harvesting machine again until most of the seed has been removed.

Keep the stand of lucerne reserved for seed perfectly free from foreign weeds, to prevent them being distributed all over the country. If raising seed for sale put it on the market clean and attractive, and in good bags. Our Northern seed has the reputation of having the best germinating properties of any in the State. Keep it so. As a sideline to help in these difficult times I advise any farmer who has suitable country to grow some seed on the lines laid out in this short paper.

Much depends on seasonable conditions, control of pests, and good judgment on the success achieved, but given normal conditions it should prove profitable.

When the boll worm was at its worst this season thousands of starlings appeared in the paddocks infested, and in a few days the pest had disappeared.

INCREASING SHEEP NUMBERS ON SMALL FARMS.

[M. J. CRONIN, Bundaleer Springs.]

With a 20in. rainfall, on a 400-acre farm, it should be possible to keep 200 ewes to lamb, and on an average about 100 dry sheep. Where possible, lucerne should be sown to secure best results. Having 50 acres planted provides most of their feed, the balance of the farm being devoted to wheat growing. During these years of low wheat prices I advocate the three-year wheat rotation, and the sowing of oats, &c., after wheat, then fed to sheep during the autumn and winter months, with chaff in self-feeders, will help to increase the carrying capacity of our farms. In fact, hand-feeding of sheep is absolutely essential on small farms in any year. and during the present period it will pay handsomely to cut at least half the wheat crop for sheep. The growing of fodder crops is also very necessary.

As to the most suitable type of ewe and ram to use: I have been using a good class large-framed pure-bred Merino ewe, mating with the Dorset Horn and Southdown ram. Results have been very satisfactory. A more valuable lamb is obtained from one of the crossbred mothers, but then that is rather a debatable question on account of the extra value of the pure-bred Merino ewe's wool. During the past two years I have tried a line of Southdown-Merino cross ewes mated with Dorset Horn and Southdown rams, and the results have been very good from an export point of view; but here again, with the present high prices ruling for Merino wool, coupled with the difficulty that confronts the average farmer in procuring the suitable crossbred

ewe, also taking into account one of the most important points—the netting of fences—the farmer, for the present at least, would be well advised to secure the large-framed pure Merino ewe to mate with either one of the pure British breeds, or with the pure Merino ram.

Fat Lamb Raising.—The greatest problem, the selection of the ewe being decided, the farmer is then confronted with the choosing of the most suitable ram. As most of the British breeds suitable for fat lamb raising are available in Australia, it is a matter of opinion which breed to select. Here again a great diversity of view arises. With the experience gained, I find the Dorset Horn lambs grow and mature earlier than the Southdown, but when both are “finished” the Down cross appears to be the most suitable for the export trade.

Pasture Development.—If raising for the export trade is the object, then the importance of good pasture cannot be over-estimated. Failure is bound to follow any attempt to “finish” at the correct weight, without an abundance of good pasture being established.

Rapid strides are being made in the heavier rainfall areas of South Australia in this direction, mainly through top-dressing, and the sowing of various clovers and grasses, &c. I experimented with Subterranean Clover, but found that the northern summers are too severe for it to grow successfully. Therefore, the only alternative lies in the establishment of the best of all fodders—lucerne—which thrives and grows well with reasonable treatment, in almost all the northern districts, and I strongly recommend its planting, even if only on a small scale.

LOWER SOUTH-EAST BRANCHES, TANTANOOLA, APRIL 11th, 1934.

MIXED FARMING IN THE SOUTH-EAST.

[R. A. HATELEY, Millicent.]

In many cases during the past few years it has proved impossible for a farmer to carry on and to pay 20 shillings in the pound while growing cereal crops alone, and for that reason I strongly advocate mixed farming. All of the optional lines to which reference will be made do not apply to each and every farm. That is not reasonable; but there are many farms in and around our district which could be successfully worked by means of mixed farming pursuits, and this applies particularly to cases where a man has sons to help him and would not be greatly concerned by additional labor costs. The following lines are all worth consideration, and, where reduced returns have rendered wheat and barley growing unprofitable, could be brought into use in conjunction with a reduction of the area previously under grain of, say, 75 per cent.:—Sheep, cattle, pigs, potatoes, poultry, and breeding of draught stock. The drawback in production of grain appears to be the problem of marketing, so I would suggest only growing a small amount, and ensuring that what is grown is the best class of the most suitable grain. If the grain is very low in price, it could be utilised with advantage for fattening sheep.

Sheep make a good and profitable line, pleasing results being obtained both for fat lamb raising as well as for fine-woolled stock. In breeding fat lambs, good-sized Comeback ewes and Border Leicester or any other ram approved for the production of fat lambs are recommended. The ewe cuts a fair fleece and produces good marketable lambs. Good results have been secured with fine wools this year. Merino lambs have sold in the local market at 15s. per head. Very often it would be of advantage to keep wethers until they are two or three years old. Along with the process of fattening it may pay to consider the growing of peas or chow moellier. The former represents a good feed which can be grown without super, although it is necessary to have the land worked well. Chow moellier is a fine winter fodder. A self-feeder with barley will work well with root crops at that time of the year.

Keeping of a few dairy cows is another line which is well worth while, and brings in ready cash. One important point is that of going in for only a well-bred class of stock. I have a preference for the Milking Shorthorn—a good milker as well as a breed suitable for the butcher. At present it may be said that it does not pay to milk cows, in view of the low price of butter; but better returns will come again, and calves often bring in a fair sum, while pigs ensure that there is no waste of the skim milk.

Pigs may also be exploited profitably. As in the case of the cow, a good breed is essential. The Large White is the best proposition for present requirements. Keep only enough pigs to use the surplus skim milk and other food which is not suitable for poultry or stock. They can be topped off with grain, up to two or three bushels per pig being recommended. One of its advantages is the fact that the pig can be bred and reared fairly quickly.

The breeding of a few draught horses will provide satisfactory returns. A good mare from the team will breed and rear a foal as well as do a considerable amount of work.

If a farmer has land which will grow potatoes he will be well advised to put in a few acres every year. They can be cultivated with little expense apart from that of digging. A man can keep his own seed for several years. No farm is complete without its quota of fowls. A good laying strain should be kept.

MOTOR TAX FROM THE PRIMARY PRODUCER'S POINT OF VIEW.

[W. M. LASLETT, Allandale East.]

At this particular time of the year when motor taxation is agitating the minds and touching the pockets of motorists throughout South Australia, we can profitably consider the question from the primary producer's point of view.

When motor taxation was increased by practically 100 per cent. it was understood the revenue derived therefrom would be used in road construction. Certainly most of it was, but chiefly in and around the city. The man on the land did not derive much benefit from the policy, for most of the produce was, and still is, carried over district roads maintained or otherwise by district councils from revenue supplied by rate-payers. Since then, and during the period of depression, motor taxation for the purpose of road construction (in itself something definite at least) has lapsed. Motor tax has now become a part of the general revenue, and although the tax is still the same, there is no guarantee that road conditions will be improved or the revenue used in that direction.

Primary producers require a means of quick transport, situated, as they are in most cases, miles from a township, and the benefits and advantages attached thereto. The man on the land realised this, and saw in the motor car the means of satisfying a long-felt want, and purchased his car when his income justified the outlay. Now he finds his income reduced by quite 50 per cent. on account of the low prices for all primary products, and his motor tax increased by 100 per cent. since he purchased his car. He is therefore faced with the necessity of paying an amount of taxation which he can ill afford, or leave his car in the shed, where it will depreciate in value, and thus deprive himself and his family of the use of a vehicle which he has purchased in order to counteract some of the hardships of a producer's lot.

It is time the primary producers throughout the State entered a united and emphatic protest against such an unjust means of collecting revenue. If the motorist is called on to make up that amount of revenue it would be a more reasonable way to collect the revenue from the road user by means of a petrol tax instead of the system now in operation which compels one to pay before he takes the vehicle on the road.

IS MIXED FARMING SCIENTIFICALLY AND ECONOMICALLY UNSOUND?

[By A. A. SASSANOWSKY (Mount Gambier.)]

The prosperity of a country or nation depends on the prosperity of the farming community. If they are only making a bare living, so will the rest of the people, for out of the land comes the wealth of the nation. It is a citizen's duty to see that the cultivating of the soil is made to pay its way.

The question is—Does the capital outlay of the farm warrant it? By mixed farming is meant cultivating the land for cereals and root crops in conjunction with dairying and sheep. The subject is not being treated as cultivation against stock. Most of the farms are worked by the owner himself, so that he has to be either in the field or with his stock.

The capital outlay can now be examined; the size of the buildings required depends on the size of the farm, but each different one has to be there, whether large or small.

For agricultural practices the following are necessary:—A horse stable, chaff shed, barn, and implement shed; these are all the large buildings required; but when stock is added in conjunction with agriculture, additional structures, such as cow shed and yards, piggery, shearing shed, and sheep yards must be provided. It may be said that the same building can be used to serve a dual purpose, but this is not so; the only building that can be used in this way is the barn and shearing shed, but the change over is a yearly cost of time and work. Having to erect the duplicate of buildings for mixed farming, they are usually of a temporary nature, to save capital, in the hopes of improving them in later years—which hopes are not always realised—so that depreciation on them is great, and the cost of repairs uses up a fair amount of profit every year, whereas if agriculture or stocks is the farmer's business, better buildings are erected and depreciation is far less. Having all these buildings for mixed farming, are they being used to the fullest extent. I say not, so that 50 per cent. of the capital is lying idle and depreciating all the time.

Implement.—For agriculture the following plant will be required:—Plough, harrows, drill, binder, harvester, waggon, grader, engine, chaffcutter, &c., and horses. For livestock, the addition of a grass mower, horserake, trolley or spring cart. These implements all cost money, and it is better to wear them out than allow them to rust out, which can easily happen in mixed farming. Take another item, fencing. What amount of fencing is required for agriculture? The boundary fence, and one paddock for the horses. It is not necessary to fence the oats from barley or potatoes. One also gains land, because about 6ft. of land is lost at each fence. With the addition of livestock the farm has to be divided into paddocks, which should be securely fenced. Too often this is not done.

For agriculture, one well or bore at the homestead is sufficient, but with the addition of livestock every paddock has to have a supply, either by windmill or pipes laid to it; if not, the stock suffer and results in a loss to the farmer.

Loss of Time.—Dairying and agriculture offer the best example. While milking, field operations are held up, and the horses are standing idle in the stable. The danger is that the farmer slurs either the milking or the ploughing, because he is always in a hurry to get to either the milking or working the horses. Not having sufficient work for his horses all the year round, as he has to save grass for his cows, the horses "are eating their heads off," and taking feed from the cows. So that the cost of growing the crop is very expensive.

The loss from a scientific point of view is that the farmer has neglected to plough the land at the right time because he wanted to save the feed for the stock. The farmer becomes unsettled in his methods; he knows he should plough, but being short of feed he does not, and the following crop is not up to the best, and results in a severe loss through trying to do two jobs.

In growing cereals and root crops there is a fixed rotation of cropping and land resting. During the time of rest, the land can be allowed to grow as much grass

and rubbish as possible, and this can be ploughed under during spring to increase the humus in the land, which is necessary to keep the land in good heart, whereas if livestock is combined with agriculture the farmer does not.

Another point of the scientific side is that in mixed operations, the farmer does not become expert on either agriculture or stock handling, whereas if he specialises on one line, he becomes more proficient as his mind is on one subject, and he seeks information on that line. Just to give one illustration of what it means for a farmer or a country to specialise. Take Denmark, for instance. During the middle of last century Denmark was in financial difficulties, but to-day it is strong, just through specialising in dairying and becoming perfect in all its methods.

The social side of the question is that mixed farming work is never finished. Life becomes a drudgery instead of a pleasure, whereas specialising either in agriculture or livestock, the producer is master of his subject, and seems to have more time to enjoy life.

Our present method of mixed farming is scientifically and economically unsound.

SORE SHOULDERS.

[By J. CARTHEW (Tantanoola).]

This paper is compiled largely from knowledge gained by experience covering a period of 18 years as a teamster, and many years of farm work. Every good horse-master takes a keen interest in the condition of the team that has to work constantly. Naturally, he will not tolerate sore shoulders, though to avoid slight sores at all times may be difficult and perhaps impossible.

In a team of horses that is well cared for, coats sleek, and well harnessed, sore shoulders are seldom found. A team in poor condition, coats sticking up, and harness curling up from being over-dried in the sun, added to other indications of negligence, nine times out of ten, investigations reveal sore shoulders.

The two cases cited rely on the two following reasons:—The man in charge of the first-mentioned team, being careful about condition of horses, harness, and other details, will be equally attentive to sores, and cure them before they become stubborn. The owner of the other team is very often neglectful about everything, and the painful results are often found under the collar.

The beginning of winter is a bad time for working horses' shoulders, owing to the fact that their coats get heavy and perspiration is increased, and as horses have to work until nearly sunset, the collars keep damp, which is bad for shoulders. Horses brought in fresh and put to work very easily scald, which is another cause of the trouble. The sagging of chains in swingle-tree work causes sores on some horses. Another cause is the use of pole strap, the collar is held too firm to the pole and chafes the shoulder.

PRECAUTIONS THAT ASSIST IN THE PREVENTION OF SORES.

Keep the collars dry by hanging them in a draught overnight and dry as much as possible during the week-end, also keep them clean and frequently soften the stuffing, using an ale bottle or hammer to hit the collar. Strike from outside, driving the stuffing towards where the collar touches the neck of the horse. This softens the collar and improves the shape. Collars doing heavy work always push outward and flatten where the most contact comes, while the shape should be slightly convex.

When working in swingle-trees, the use of a backband eases the tendency for the sagging of chains, and when in leading harness have a strong bellyband, so that it will stand tightening to an extent that will make the draught slightly down, thereby bringing the pressure evenly balanced on the shoulder.

When first working horses that have been spelling, wash the shoulders at midday and night while still warm from work, and if a horse is thin-skinned and the skin threatens to break, always make a practice of washing.

A horse that has to do hard work should be kept in hard condition. Backbands, bellybands, and collar stuffing are important, but feeding must not be neglected, which should be ample and good,

The following is a successful remedy for most shoulders that have broken open from chafe, scald, or bruises. Wash the wound immediately on ceasing work, sufficiently to thoroughly clean the sore part. In the morning, before harnessing, repeat the washing, leaving a good lather of soap on the shoulder; this has a cleansing and soothing effect, and after a few days the scar begins to heal. Be sure that the collar is not projecting on the wound; if so, it requires easing. Horses with very bad shoulders have been cured by washing at the trough dinner time and night with water only, but the use of soap is an improvement on water only.

Gall cure is a very good remedy for small wounds, on the shoulders or back. It should be applied before and after work each day. Keep the collar scraped clean when using gall cure, but do not use any water on the wound with this remedy. A false collar reduces friction and is a good thing for a thin-skinned horse that is chafing. It is claimed that a tanned sheepskin makes an excellent false collar; this prevents the collar from absorbing perspiration, besides preventing chafing, providing it is kept soft and pliable.

As horses have to be given a drink at dinner time and evening, there is no inconvenience in having to dip out a bowl of water and wash the shoulders with a cloth with water from the trough. In some cases shoulder trouble is due to the horse being too free for the rest of the team. In such a case lengthen the chains sufficiently to steady him; when he is in front the couplings have a check on him, and he will cool down to steady work in most cases.

Experience proves that the remedies mentioned in this article effect a more permanent cure if the horse is kept at work, and for this reason I am opposed to spelling the horse, which will generally break out in the shoulders when put to work again.

A SCARAB BEETLE (*Aphodius tasmaniae* Hope.)*

DESTRUCTIVE TO PASTURES IN THE SOUTH-EAST OF SOUTH AUSTRALIA.

[By D. C. SWAN, B.Sc., Waite Agricultural Research Institute, University of Adelaide.]

INTRODUCTION.

The agricultural development of the South-East portion of South Australia has resulted in the increase of areas under permanent pasture and their improvement by top-dressing with appropriate artificial fertilisers. This has made it possible

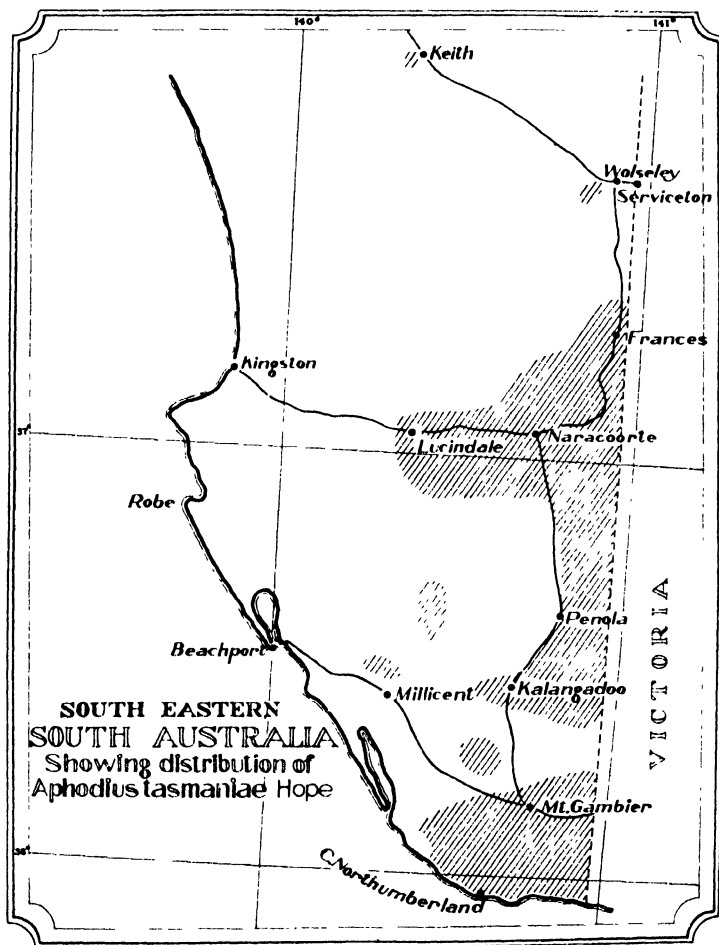

Fig. I. Showing general distribution of *Aphodius tasmaniae* in South Australia. (From information supplied by Mr. E. S. Alcock.)

*Specimens obtained from Mount Gambier district in February, 1932, were identified by the late Mr. A. M. Lea as *Aphodius howitti* Hope (vide Davidson, *Journ. Agric. Sth. Australia*, October, 1933, p. 286). *A. tasmaniae* is referred to as a pest of lawns and pastures in the Sixth Annual Report, C'wealth C.S.I.R. 1932, p. 23. Dr. A. J. Nicholson, Acting Chief, Division of Economic Entomology, informs us that the synonymy given in the collection of the division is as follows:—

- Aphodius tasmaniae* Hope
- = *A. howitti* Hope
- = *A. andersoni* Blkb.

to carry an increased number of sheep to the acre (2½-4). It is well known that a marked increase in the stock-carrying capacity of an area introduces new problems. For example, the degree of infestation of sheep with intestinal (worm) parasites may increase; the botanical composition of the pasture is changed, which influences the kinds and numbers of insects associated with it.

The scarab beetle *Aphodius tasmaniae* is a native insect and presumably has always been present in the South-East. It appears to have increased in numbers during recent years, and at the present time its larvae (grubs) are a pest in pastures in certain districts (Fig. 1).

In a letter dated September 30th, 1930, the Secretary of the Stockowners' Association of South Australia drew the attention of the Australian Pastoral Research Trust Ltd. to the importance of the matter and the desirability of an investigation of the problem being carried out. This letter was referred to the Commonwealth Council for Scientific and Industrial Research, which body referred the matter to the Waite Institute.

Fig. II. Showing habits of *Aphodius tasmaniae* in pasture.

Owing to several inquiries being received about this time, a short general article on "White Grubs" was written (Davidson, J., *Journal Agric.*, S. Australia, Vol. 34, 224-227).

In a letter dated July 28th, 1933, the Secretary of the Stockowners' Association of South Australia stated that the council had been again discussing the matter, as a result of inquiries which had been received by them.

The observations which are embodied in this paper show the present position regarding the investigations on the problem.

Aphodius belongs to a large family of beetles (Fam. Scarabaeidae) which includes scarabs, cockchafers, June beetles, &c. Their larvae are characteristic stout, whitish grubs, usually curled in repose, and often referred to as "white grubs." They live in the soil, feeding on the roots of plants. Adult scarabs often occur in large numbers on foliage, to which they may do considerable damage.

In the case of the true cockchafer the larvae work beneath the soil surface. In the species under discussion the larva lives in a vertical burrow up to 8 in. in depth, but at night it emerges and moves about at the surface. Portions of leaves of the pasture plants are bitten off, and carried down to the bottom of the tunnel, where they are apparently consumed at leisure. By day the larvae are found in the tunnels. The soil that is excavated in making the burrows is spread in a crumbly pile at the mouth of the burrows. In areas where the degree of infestation of the pasture is high, a large amount of soil may be thrown out of the burrows; it may be sufficient completely to cover the young growth of the pasture. The soil surface, in effect, may be covered by a loose mulch nearly 1 in. in depth. If this occurs in the winter, when growth of the pasture is slow, the regeneration of pasture already damaged by the feeding activity of the grubs may be prevented, resulting in bare patches. The part of the State where this insect has been observed is indicated in the map (Fig. 1). The first examination of the area was made in April, 1933, by Dr. J. Davidson, when the biological details given above were made out. At the time of his visit, the number of burrows in a square foot of soil surface in a local area, was estimated at 150.

LIFE HISTORY.

The development of the beetle from egg to adult apparently takes one year. No data are available in regard to the eggs or oviposition. The adult beetles, after emerging from the pupae in the soil, remain quiescent for a period of some days, during which the chitin hardens and the maturation of the eggs takes place. Dr. Davidson obtained adults in the field in February, 1934. They were kept in the laboratory in damp soil for a fortnight, during which period no signs of oviposition could be detected; the males mated freely with the females. At the end of a fortnight the ovaries of some females were dissected out. Each ovary consisted of six ovarioles. Each ovariole contained one large egg, and one about half as large, but neither egg seemed ready for oviposition. This suggests that a small number (about 20) eggs are laid by each female. The stimulus to leave the soil on the mating flight is doubtless associated with definite weather conditions; the flights always take place during warm, humid nights. The first flight in the Mount Gambier district in 1934 took place on February 21st, with a smaller flight on March 7th. These flights which are later than usual were observed by Mr. E. S. Alcock. The summer was exceptionally hot and dry. The mean annual rainfall and temperature for Mount Gambier are given in Figure 3, together with the same data for the year 1933-34.

Mr. Alcock has supplied the following details of past flights:—

1931	February 12	Very numerous
1932	February 9 and 12	Very numerous
1933	February 9 and 30	Very numerous
1934	February 21	Numerous
	March 7	Small flight

These flights involve great numbers and the beetles are attracted to lights. They may be so thick as to make car driving through them at night a difficult matter.

Species of *Aphodius* and its relatives are known in many parts of the world, and are, in general, dung feeders. It is the opinion of some farmers in the South-East that females of *Aphodius tasmaniae* select areas of pasture specially rich in dung whereon to oviposit. Thus heavy infestations of larvae may occur near fences. Sheep tend to congregate at fixed spots at night, especially on rises and hill slopes, and the sites of these "sheep camps" may be favored. The affected pastures which have been examined consist of subterranean clover (*Trifolium subterraneum*) which may comprise up to 80 per cent. of the pasture, the remainder being chiefly annual grasses. The soil of the region is sandy, with

some areas of volcanic origin, and in these soils burrowing by the larvae is an easy matter. The rainfall of Mount Gambier (Fig. 3) is typical of the places in which *Aphodius* is present.

THE LARVAE.*

These appear in the field in the autumn, and their effect on the pastures becomes apparent about April. They are active, with well developed legs (Figure 4). They crawl in the normal upright position. The head is broad and is used to push the excavated soil out of the burrow. They feed throughout the winter, and reach the last instar in early spring. The writer visited the South-East in late September, by which time feeding was completed. The larvae were found at the

Fig. III. Rainfall and Temperature for Mount Gambier, 1933-34. It will be seen that the rainfall was considerably below normal, which may account for the smaller and later flight of beetles in February, 1934.

bottom of their burrows, mostly at a depth of about 6in. Only in a small proportion of burrows were small pieces of leaves found. The grubs were then a creamy-yellow color, the usual dark abdominal contents having been digested. They were quiescent, awaiting pupation. The habit of casting earth from the burrows was not in evidence at that time, but numerous larvae were found in the soil in bare patches in the paddock, which were almost denuded of pasture. Larvae were found in burrows that were many yards from any growing plants. In feeding, it is presumed that the larvae extend outwards, digging new burrows as needed, since the damage occurs mostly in definite patches, which gradually increase in area. Their damage to the pasture results from two effects, directly as a result of biting off the upper parts of the plants, and secondly by burying with soil many of the young seedlings.

* Vide also Report, Waite Agric. Res. Inst., 1925/32, page 60.

It may be noted that no natural enemy of importance was seen in the field. In some places a proportion of 5-20 per cent. of the mature larvae were found killed by a fungus; they were pink in colour.

DISTRIBUTION OF LARVAE IN THE FIELD.

As well as being found in association with subterranean clover pastures, the larvae may occur in areas newly planted with a cereals crop. They are troublesome in the greens of the Mount Gaubier golf links. Larvae are usually not

Fig. IV. *Aphodius tasmanicus* larva, and detail of mandibles.

present in the same situation in two consecutive years; an interval of several years may intervene between successive infestations. It has been noted by some farmers that the thorough turning over of soil, as a result of the tunnelling of this beetle, improves the fertility of the soil in the year following its presence.

THE PUPA (Figure 5).

From October until mid-December no change in the larvae takes place. The first pupae were found at the beginning of January, 1934. They are found at the bottom of the larvae tunnels, each pupa lying in a terminal rounded cell (Figure 3).

THE ADULT.

The first adults in 1934 were taken on January 15th, but the bulk of them generally emerge early in February, if conditions are favorable. They remain, as previously described, *in situ* in the soil for some time. The complete life-cycle, as far as it can be reconstructed, is shown schematically in Figure 2. The adult is a rather slender scarab about 10 mm. (0.4in.) long (Figure 6). The dorsal surface is glabrous, and dark-brown in color. The mouthparts are concealed by the shovel-like clypeus. The eyes are inconspicuous, the greatest surface being ventral. The legs are strong and spurred, the forelegs specially so. Males and females are similar, but in the former the pronotum is somewhat wider than the after body. In the female (Figure 6) it is the same width. The adults burrow readily. In an open petri-dish in the laboratory, they crawled actively, but showed no desire to fly, and died in two days (average temperature 73°F., average R.H. 79). The mouth-parts are weakly developed, and it would seem that if the adults

Fig. V. *Aphodius tasmaniae*, pupa.

feed at all, their diet must consist of liquid food. The mandibles are slightly chitinised, with a small molar area and a large flattened upper lobe, and are altogether unsuitable for chewing vegetable food.

As mentioned above, the adults leave the soil and a mass flight takes place. The eggs laid by the female apparently hatch after the onset of the autumn rains, when the moisture content of the soil has become adequate.

CONTROL MEASURES.

In common with other field pests which occur over wide areas, the economical control of this insect is difficult. Measures should be concentrated upon local areas where a heavy infestation is present. A spray of 7lbs. lead arsenate to 100galls. of water was found to be an effective control of the pest in the golf

greens at Mount Gambier. In the field, two objections to this method exist, first, the expense, and second, the delay before the treated pasture can be used for grazing. Such areas could be fenced and the method tried if the saving of the pasture justifies the expense. The most promising control of such areas appears to lie in judicious cultivation. Some farmers already employ this with success, and therefore do not regard the pest as serious. It will be seen from the diagram of the life-cycle (Figure 2) that the mature larvae and pupae lie in the soil until

Fig. VI. *Aphodius tasmaniae*, adult female.

early January. These stages are susceptible to heat and dryness. In the laboratory in summer, the larvae died in two days when exposed in open dishes, and the pupae are less resistant. Deep cultivation in early summer should therefore cause a big mortality in these stages. Similar treatment of infested pasture in the early stages of attack should do much to rid it of the young larvae, if carried out in dry hot weather in autumn. It is probable that this is a better time for such treatment than early summer, as the pest is dealt with before the damage is done. The summer treatment will not have much effect on the ultimate number of adults in the countryside, owing to the many areas of slight infestation that will not be treated.

ACKNOWLEDGMENTS.

Much of the preliminary knowledge of *Aphodius tasmaniae* was obtained by Dr. Davidson in the course of two visits to the South-East, and the facts he obtained are embodied in this paper. He has greatly assisted the author by discussing all phases of the problem, and by making many useful suggestions. It also gives him pleasure to acknowledge the interest and assistance of Mr. E. S. Alecock, of Mount Gambier, Agricultural Instructor of the Department of Agriculture. Mr. Alecock has been the personal conductor of both Dr. Davidson and the author on the various visits made to the South East, and his knowledge of the district was most helpful. Further, Mr. Alecock kept a close watch on the progress of the larvae in the field, and the specimens sent by him from time to time have made it possible to place many points in the duration of the life-cycle. Dr. J. G. Davies, Agrostologist at the Waite Institute, has kindly supplied information relating to the pastures. Finally, a number of farmers, particularly Mr. A. A. Sassanowsky, of Mount Gambier, have rendered assistance and information during visits to their districts.

SUMMARY.

1. The problem of the "Scarab Grass-grub" (*Aphodius tasmaniae*) in the South East of South Australia is discussed.
2. It is suggested that its numbers have increased following improvement and increased stocking of the permanent pastures of the district.
3. The life-cycle of the beetle is discussed.
4. Some suggestions are made regarding control measures.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 3 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed. Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 5 Test.—Morning—1 $\frac{1}{2}$ ozs. wheat per bird.

Evening—1 $\frac{1}{2}$ ozs. wheat per bird. Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to March 31st, 1934.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

No. of Test.	No. Eggs Laid April 1st to February 28th.	No. Eggs Laid Month March.	Total Eggs Laid April 1st to March 31st.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 5.—BATHURST BURR.

(*Xanthium spinosum*, L.)

Xanthium spinosum was introduced into Australia in the forties, and is believed to have originated from burrs carried in the tails of horses imported from Valparaiso, South America. Within a few years it had spread to Bathurst, New South Wales, and the plant has come to be known throughout Australia as Bathurst Burr. It is a noxious weed in all of the States, and is objectionable

Bathurst Burr, showing general habit. (See colored plate opposite.)

mainly on account of the burrs, large numbers of which are formed on each plant. The burrs, which are egg-shaped and about $\frac{1}{4}$ - $\frac{1}{2}$ in. long, are covered with hooked spines by means of which they cling very tenaciously to clothing and to the coats and tails of animals. They are especially troublesome in wool, and the value of wool may be depreciated thereby; in fact, the weed has been responsible in the past for considerable financial losses both in this country and in South Africa. Owing to the ease with which the seed-containing burrs are distributed, the plant has been unconsciously spread by man throughout most

BATHURST BURR.

(*Xanthium spinosum* L.)

A.—Leaf, showing the strong trifid spines (natural size).

B.—Fruiting head (Burr), covered with prickles (enlarged).

warm parts of the world, and to such an extent that there has been some doubt as to its native home. It is believed to have come originally from Chili in South America, but it now occurs extensively in Europe, Asia, Africa, America, and Australia.

The Bathurst Burr is easily recognisable by its erect much-branched habit of growth, its lanceolate mostly 3-5-lobed leaves which are dark-green and prominently veined above but greyish-white below, its three-branched yellow spines, and by the burrs which are clustered in the leaf-axils. All of these characters are well shown in the accompanying illustrations.

Botanical Name and Classification.—*Xanthium* (from the Greek, *xanthos*, yellow) is on account of a yellow coloring matter obtainable from certain species and said to have been used by the ancients for dyeing the hair; *spinosum* refers, of course, to the presence of spines. The plant is a member of the *Compositae* or Thistle family, but belongs to a different tribe from that including the thistles proper. Some peculiarities of this family were mentioned in the course of a description of the Star and Saffron thistles in the issue of the *Journal* of February last. It was pointed out there that the so-called "flower" of *Compositae* is really an aggregation of tiny flowers or florets, surrounded and protected by an involucre of bracts. Now the compositous nature of Bathurst Burr is not at first evident; it is difficult to recognise in the burr of *Xanthium* the structure of a compositous flower-head. Nevertheless the burr is such a flower-head; it consists of a pair of female florets—or of a pair of fruitlets derived from these—enclosed within a spiny covering made up of the fused involucre bracts. The compositous structure is, however, more clearly revealed if the uppermost leaf axils are examined with the aid of a magnifying glass. Here, in place of the burrs, are formed small heads of male florets of a more typically compositous pattern; the individual florets, though small, are numerous, and the surrounding involucre bracts are free from one another. Thus *Xanthium* is peculiar in having unisexual florets, the males and females being grouped in distinct heads with the former towards the tips of the branches, while the latter are situated lower down and develop, when ripe, into the characteristic burrs. The inconspicuous nature of the heads, both male and female, is associated with the fact that the *Xanthiums* are pollinated by wind and not by insect agency.

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,
SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A

MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK.

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling and long trouble-free service.

TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

The Genus.—There are several species of *Xanthium*, all of which are annual, and most of which belong to the Mediterranean region. The only other species present in this State is *Xanthium californicum*, Greene, a native of California and known as Californian Burr. It differs from *X. spinosum* in being devoid of spines on the stems and in having broader leaves and somewhat larger burrs, each of which bears two conspicuous incurved beaks at the end. The Noogoora Burr of the Eastern States is said, by some authorities, to be *X. strumarium*, L., a native of Europe, and by others is named *X. pungens*, Wallr., which belongs to eastern North America. Possibly both species occur there.

Botanical Description.—*X. spinosum* is a rigid much-branched annual of 1ft. to 2ft., studded with numerous strong trifid spines usually opposite, in pairs, or rarely solitary, divaricate, placed at the base of the leaves but rather within the petiole. Leaves lanceolate, trifid, with the central lobe much longer than the lateral ones, slightly scabrous above, white tomentose underneath. Flowerheads in axillary clusters or almost solitary, the upper ones male, the lower female; these are sessile, forming when in fruit oblong burrs about $\frac{1}{2}$ in. long covered with hooked prickles, the terminal conical beaks exceedingly short, often both reduced to mere tubercles or one only slightly elongated. Period of flowering: February to July.

Properties.—The Bathurst Burr is said to be poisonous, but owing to the spines is seldom eaten by stock. It is mainly on account of the burrs that the plant is so very serious a pest. Each burr contains two seeds, one of which germinates the following season while the other does not develop until the second or third year. The burrs represent an extremely efficient method of dispersal, and this is evidenced by the very wide distribution of the plant throughout the world. Thus its spread through Europe from the East has been described:—

“In 1828 it was brought into Wallachia by the Cossack horses whose manes and tails were covered with the burrs. It travelled in Hungarian wool, and in cattle from the same region to Regensburg, and on to Hamburg, appearing here and there on the way.”

While the spread of the plant is mainly by animal agency, the burrs may be carried by floodwaters, as is shown by the frequent occurrence of large numbers of plants along the banks of creeks.

As regards Bathurst Burr and its relation to wool, the writer is indebted, for the following remarks, to Mr. A. H. Codrington, Senior Lecturer in Wool-classing at the Adelaide School of Mines:—

Much of the Bathurst Burr is eliminated from wool during the scouring process, and removal of the remainder is effected either by the application to worsted carders, or by special devices for removing and crushing this impurity. Removal of the subdivided particles of crushed burrs is then a function of the combing machines. As regards the effect of Bathurst Burr on the value of combing wool, unless the quantity present in the fleece is sufficient to reduce the wool both in type and value to a considerable extent, the estimated price of grease wool is only lowered in proportion to the percentage or weight of the burr present, as such wool would not undergo the carbonizing process, which would mean a considerable expense. The Bathurst Burr is not such a serious impurity in wool as Burr Trefoil, because the latter may in some cases require to be removed by carbonization.

Eradication.—The weed is an annual, and spreads entirely by seed. It is easily kept under by cultivation methods, and so is not a serious pest on agricultural land. It is in pastoral country that the weed is so formidable, and the only sure method of eradication is to prevent the plants from developing seeds. Where possible, therefore, the plants should be cut down and burned before the burrs have ripened. Sheep pastured on burr country should not be transferred to clean lands without being shorn.

IMPROVING THE BUTTERFAT STANDARD OF OUR DAIRY HERDS.

[Paper read by W. H. DOWNES, H.D.A., Dairy Instructor, at the Conference of Lower South-East Branches of the Agricultural Bureau, Tantanoola, April 11th.]

In view of the very depressed condition of the dairy produce market at the present time, it may appear to be the wrong time to preach the gospel of improvement, especially along lines which tend to create increased production in a commodity with which the world already seems to be too well supplied.

The present lot of the dairy farmer is not an enviable one; he has to work just as hard, or even harder, than before for an income so low that it is ridiculously out of all proportion for his labor, and besides representing less than a poor living wage will not enable him to meet ordinary farm expenses in most instances. While our sympathies are with those who are experiencing extreme hardships in this industry just now, in reviewing the past it must be admitted that the position has not always been so hopeless. Many past seasons have proved the advisability or necessity of including dairying among other mixed farming pursuits to augment the general farm revenue. Indeed, it is very doubtful whether many of those engaged in agricultural pursuits would have survived the depression without some assistance from dairying. The very fact that a regular income has been derived from this source—small though it may have been—has undoubtedly enabled a great majority to carry on. The principal factor on which the future progress and success of dairying depends is not so much increased production, but economic production, on the soundest lines, and in the truest sense of all that it implies.

Probably there has never been a time when improvement along these lines has been more vitally necessary than to-day. For the present, such improvement should naturally take place along avenues of the least possible expenditure. One of the first steps in this laudable direction will, however, involve a fair expenditure, but the farmer who carries it will be more than amply compensated for his first outlay.

THE USE OF A PURE-BRED HERD SIRE.

I refer to the improvement of the dairy herd through the introduction of a well-bred sire of recognised quality descended from ancestors of noted butterfat production. During past years this matter did not receive the attention it certainly deserved, with the result that district herds, generally speaking, are nothing to be proud of, neither as regards their general appearance nor their capacity to produce. In addition, it is true that many farmers failed to embrace the opportunity to improve their herds by this means when dairy prices were better than they are to-day.

The small number of high-class bulls purchased in a district of this size is disappointing, and will need to be greatly augmented before much in the way of general herd improvement can be achieved. The type or strain of bull used counts considerably. It has frequently been proved that the merits of a fine-quality bull have never been appreciated fully until after the animal has been disposed of. The qualities of most highly-bred animals are usually very firmly fixed, far reaching, and readily transmissible to many generations of their progeny. There are many instances which could be quoted in support of this statement, but I will merely quote one:—In the year 1919 a World's Champion Jersey Cow, "Wagga Gladys," was born, and her production figures will easily bear repeating. During the year 1927, as an 8-year old, she established a world's record for the breed by yielding 1,149lbs. of butterfat in a lactation period of 365 days. For five consecutive periods her production averaged well over 800lbs. of butterfat. Her

sire, "Goddington Noble XV.," was an imported bull from the famous stud of that name. This bull was the sire of a long line of heavy producers, and the fact that 19 of his daughters averaged 566lbs. of butterfat in lactation periods of 273 days should require no further recommendation. "Posey V. of Richmond," a granddaughter of "Gladys" and a great-granddaughter of "Goddington Noble," created a new record for the breed with 800lbs. of butterfat as a 3-year-old in an ordinary lactation period. "Richmond Fox," a son of "Gladys" and the sire of "Posey V.," is in use at the Hawkesbury College stud, and besides possessing exceptionally fine outward qualities is proving very satisfactory as a begetter of heavy producers. These facts serve to indicate how deeply and strongly seated are the production qualities in well-bred animals, and further, the ability and ease with which they transmit these characteristics to their progeny. Dairymen in this State have the added advantage of the Bull Subsidy Scheme to assist them in purchasing the right class of animal with which to uplift the quality of their herds, and they should utilise it to the fullest extent. In making the purchase of a bull, a personal inspection is strongly recommended if possible. A buyer can then determine whether the bull is suitable, or the type required, and may also satisfy himself with regard to details relative to breeding, butterfat production, etc.

THE SELECTION OF A HERD SIRE.

The buyer, if making his selection personally—with a number of animals from which to choose—will do well to observe the following points:—The bull should be well grown for his age, and possess a well-balanced conformation. A predominance of masculinity with an absence of viciousness should be noticed. There should be a fairly massive appearance throughout, without running to undue fleshiness or fat. A nice head appearance, a massive neck, and a roomy, well-sprung barrel, supported on strong, straight legs. The bull should walk with an active carriage, and the skin should be soft and smoothly coated—all points which usually denote good health. In studying the pedigree it should be apparent that the bull is descended from a strain of heavy-producing ancestors on both sides. As the breeding up of better producers takes some considerable time, the purchase of a quality bull is of foremost importance. Other important factors to be considered in reaching the desired goal of increased herd production obviously include feeding and management.

FEEDING.

Improvement in feeding methods can be carried out in two directions, viz.: (1) better facilities for pasture, and (2) improved methods of fodder conservation. Pasture really represents the dairyman's main crop, and as such its improvement should receive early consideration. One of the first essentials towards the better management of pasture is the subdivision of large paddocks into smaller plots, and provided that posts are available, and the farmer has the time at his disposal to carry out the work, this should not prove a very costly item. The advantages of having a greater number of small paddocks available should at once be apparent. It facilitates rotational grazing or regular change of pasture for stock, which is far more preferable, and will prove of greater benefit than if they are permitted to graze over a large area. The nature or quality of the pasture can be more easily improved as the farmer can usually concentrate on the smaller area, and the proper treatment of pastures after being grazed can be more easily accomplished. When time and money permits, each paddock can be sown down eventually with a suitable mixture of certified seed, and later subjected to a proper system of top-dressing. During seasons of pasture scarcity and lack of cultivated green crops, the milk supply will rapidly fall unless supplemented by food in some other form. It is for this reason that dairymen are urged to conserve fodder for lean periods, and though hay seems to be fairly popular as a means for keeping cows full and in good condition, owing to its dry nature it cannot be strongly recommended as a milk-producing food.

ENSILAGE.

Ensilage is becoming increasingly popular in this State as a fodder, principally for cows and, by reason of its succulent nature when properly made, provides the best substitute for grass or greenfeed. Where a small herd is concerned, the cost of erecting a suitable silo would be a prohibitive item, but there is nothing to prevent the building of an ensilage stack. Most cereals are excellently suited for the making of silage, but in addition these grass and various other fodder crops may be utilised with satisfactory results. In building a silage stack, bear in mind that a fair percentage of the sides and top of the stack will be waste material. On this account it is advisable to make stacks of large size, because the proportion of wastage will be less on one large stack than on two half the size. Most fodders should be cut for ensilage at a stage just after flowering, when the grain is in the milky or doughy stage. It is important when stacking the material to compress it very thoroughly, especially round the sides. In this way the stack is more or less sealed from the ingress of air likely to cause delayed fermentation and a greater percentage of mouldy fodder. Guide poles may be utilised to keep the stack straight whilst building and settlement is in progress. The quality of the silage depends on the quality of the crop ensiled, but many crops have a tendency to improve during the curing process, thereby proving far more palatable to stock. It is surprising how well cows maintain or even increase their production when fed with ensilage.

ADVANTAGES OF ENSILAGE.

Some of the chief reasons why ensilage should commend itself to dairymen as a fodder distinctly superior to hay or chaff are:—Ensilage on account of its succulent nature appeals to the palate of cows more readily, and tends to keep them in heavier production than any fodder of a drier nature. A much greater weight of fodder is secured as fully 80 per cent. of the original green weight is retained. A stack or silo of well-cured silage will remain in good condition for a number of years provided it is kept well sealed. Once properly cured the danger of fire is nil. It is not a very attractive fodder for the ravages of mice. During excessively dry seasons silage will keep cows in good laxative condition, thereby minimising losses caused by dry bible. Waste green material, such as thistles, may be used for making silage, and therefore converted into useful fodder. Weeds may be better kept in check by reason of the fact that they are harvested with the ensilage crop before their seeds have had an opportunity to ripen.

GENERAL MANAGEMENT.

Apart from the actual feeding, there are several other important points in connection with the successful care of the herd which are well worthy of consideration. Regular milking hours, proper resting periods for dry cows, the rearing of healthy calves, and a plentiful supply of good water may all be included. Cows are animals of regular habit, and respond much better to regular treatment. Milking should be carried out at regular hours, and each milking spaced to as near a 12-hour interval as convenient. Gentle treatment, and the absence of noise at all times, are factors which favor the best production. A rest of from two to three months between lactations is absolutely essential in order that the cows may produce well during subsequent lactation periods. The work of milk production is a heavy drain on an animal's system, and a cow that does not receive this rest usually has not had sufficient time to replenish her system, and she comes into milk again in such a poor condition as to be totally unfitted for a period of sustained heavy production. Dry cows should be pastured on medium feed so that they may obtain sufficient exercise whilst securing their food to maintain them in good muscular condition. They should be under continual observation during this period so that on the first sign of any calving trouble, immediate attention may be given.

REARING THE CALVES.

The healthy heifer calves from the best cows should receive first consideration, but if there is still a surplus of milk it will probably pay to rear even more of them, particularly where land values are low. Careful feeding tends to minimise losses among young stock, and is productive of well grown, thrifty calves. Cleanliness, combined with regular feeding hours and a uniform ration of sweet milk at the correct temperature, are factors favoring this desirable result. The common danger of a greedy calf over-gorging, with the frequent result of sickness or death, may be avoided by using separate feeding vessels for each calf. A ration of 10lbs. to 12lbs. of whole milk, equally divided into two feeds per day is recommended during the first three weeks, and if possible the mother's milk or beastings provided during the first week of the young calf's life. During the fourth week a gradual change may be made to skim milk by breaking down the whole milk each day with a slightly increased quantity of skim. When the calves have been placed on a ration of skim milk, it will be advisable to add some fatty substitute to replace the food value of the cream removed. The addition of a quarter to half a pint of limewater to each feed is of great benefit to young calves, because it tends to induce better growth and bone development.

HERD TESTING.

This is the only practical means whereby a dairyman can check the individual production of his cows, and the man who has not sufficient interest in his herd to have them tested is working in the dark. It is indeed a pity that no testing associations are operating in the South-East, for there surely must be tremendous scope for improvement in this direction. When taken seriously, testing becomes very interesting, and is full of surprises to even the initiated or the man who considers himself a good judge of dairy stock. Frequently, as a result of not employing a regular herd test, good producers are disposed of and wasters are often retained. Each individual cow when tested becomes a separate unit of the herd, and according to her value as a producer so a definite value may be placed on her. Testing enables a dairyman to weed out the non-paying members of the herd, and concentrate only on those which prove profitable. It is also a distinct guide to feeding correctly and sufficiently, and will definitely show the producing capabilities of the herd sire when his heifers reach their age of production. There is much to be said in favor of testing, the cost of which is comparatively trifling when compared to the great losses at present involved through feeding, handling, and milking the wrong type of cow.

SORE SHOULDERS.

"The successful prevention of sore shoulders is wrapped up in close attention to the following matters" (says Mr. A. H. Robin, B.V.Sc., Government Veterinary Officer):—

1. Proper and gradual "conditioning" of the animal for work.—As an aid to hardening or toughening the skin of the shoulders, these parts can be swabbed daily with a strong solution of salt or a decoction of wattle bark, immediately after removing the collar.

2. Proper fitting of the collar.—Every horse requires to have his own collar, which should be properly and carefully fitted to him, and any necessary adjustments should be made from time to time as the horse gains or loses in flesh. Remember that a collar that "fits" a horse when he is in good flesh will not fit him when he gets poor, and *vice versa*.

3. The shoulders where the collar sits must by regular daily grooming (before the day's work is begun) be kept clean and free from accumulations of dried sweat, grime, &c., that are likely to set up chafing of the skin. Likewise, the linings and stuffing of the collar should by regular attention be kept clean and soft, instead of being allowed to become caked and hard with sweat, grime, &c.

HISTORY OF KYBYBOLITE STATION.

ESTABLISHMENT OF KYBYBOLITE EXPERIMENTAL FARM.

[By E. S. ALCOCK, Agricultural Instructor.]

The Kybybolite Station, which is situated in the South-Eastern district of South Australia, is in the hundred of Binnun, 13 miles north-east of the township of Naracoorte, and about 80 miles from Mount Gambier on the Mount Gambier-Wolseley railway line.

This property was originally selected by Edward Townsend in the 40's. No records of the date of his arrival are available. However, records state that the name was changed in 1849 from Townsend's Run to Kybybolite.

Prior to July 1st, 1851, pastoral lands were held in the South-East under what were known as "Occupation Licences." These cost £5 per annum, with the addition of annual charges for livestock. For every ram, ewe, wether, or weaned lamb the sum of 1d. was paid; for every bull, cow, ox, steer, heifer, or foal under six months, the sum of 6d.; and for every horse, gelding, mare, or foal over the age of six months, the sum of 2s. 6d.

It is also interesting to note that the pastoral leases issued after July, 1851, were charged according to the classification of the land—as first-class land, £1 per square mile per annum; second class, 15s. per square mile; and third class, 10s. per square mile. This area was classed as second-class land in those early days.

Records show that Edward Townsend was allotted lease No. 163, 64 miles of waste lands, from the Crown on July 1st, 1851, for a term of 14 years at an annual rental of £48 per annum.

He apparently lived over the border, since his address was Victoria, and he sold this lease for £10,000 on February 2nd, 1855, to Mr. Heighway Jones, a Welshman, and a brother of Henry Jones, who took up Binnun, Conkar, and Cadnite. Mr. H. Jones surrendered the lease upon condition of receiving a new lease of the same lands on May 31st, 1859. The new lease dated from July 1st, 1859, for a period of six years, carrying an annual rental of £181 6s. 8d. per annum, or £2 16s. 8d. per square mile.

This lease carried a condition which allowed the original lessee to sell, and Mr. Jones took advantage of this on June 10th, 1863, when he disposed of all his interest to James Affleck. A new lease was made out in the name of James Affleck on June 10th, 1863, carrying the same conditions, and this lease expired in 1865.

The land was again taken up by James Affleck, and a new lease was issued for five years, bearing an annual rental of £354 12s., or £5 10s. 10d. per square mile, on July 1st, 1865.

Then in 1869 this lease was subdivided by Surveyor Gosse as the hundred of Binnun. Kybybolite Head Station was situated on section 57 (608 acres), the freehold of which was purchased at auction by James Affleck for £2,280, or £3 15s. per acre, on July 21st, 1870. He also purchased most of the adjoining sections at the same time.

James Affleck died on February 15th, 1875, and this property was transferred to his executors, H. G. Cattanaach and R. Smith, in 1879. The property, which contained 26,614 acres, was purchased by George Stanley Harris from James Affleck's executors for £62,500, or £1 19s. 2d. per acre, in 1885.

Then, in 1888, Mr. Harris leased this station to Mr. Richard Kiddle, who purchased 26,783 acres from Mr. Harris for £52,500, or £1 19s. 8d. per acre, in 1890.

In 1905 the land was re-purchased by the Government from Mr. Kiddle for the sum of £63,498, or £2 7s. 6d. per acre, for closer settlement.

The original homestead was about three miles further north than where the present house stands. This was built by Mr. J. Affleck about 1861. There is no record of the name of the contractor, but it is understood that Henry Holmes and Harry Smith assisted with the building. It is a fine two-storey building of local stone, and is in a good state of preservation. The homesteads at Crower and Cairnbank were built off the same plan; both these properties are in the Lucindale district; and also Mortat, in Victoria.

Like most station properties, there is a private cemetery, and the one at Kybybolite has several graves in it. Very few of the station buildings are standing to-day, but the old buggy shed and stable are now used for barns, and the loft for storing odds and ends. Portion of the old wool shed and sheep yards are still in use, but the men's hut and other buildings have been pulled down and the material used where possible in the erection of more serviceable buildings. The immediate neighbors during the late sixties were H. and D. O. Jones, who owned Binnun in the north and Conkar and Naracoorte in the west. The former belonged to H. and D. O. Jones, and the latter to Thomas Magarey, whilst Hynam and Broadmeadows, belong to Adam Smith, bounded it on the south, and the Victorian border on the east.

EARLY RECORDS OF STOCK AND RETURNS.

It is not easy to secure reliable information regarding the numbers of stock carried on this property in the early station days, and the same remarks apply to the wool cut annually. However, the following have been supplied from various sources, and are as near as I have been able to get at present:—

Mr. R. Kiddle carried approximately 11,000 sheep, which cut an average of about 6lbs. of wool per head, and about 200 bales of wool. Another report states that they celebrated the occasion when the 300 bale mark was reached. It is also well known that they had to purchase the bulk of their ration sheep in those days.

These statements must be near the mark, for records of the clearing sale of this property, which was held on March 23, 1905, showed that they sold 12,992 sheep, which realised £7,482 1s. 3d., or 11s. 7d. per head; also 95 cattle for £313 14s. 6d., or £3 5s. 11d. each; and also 40 horses. These sheep would also include the previous season's surplus. Mr. Kiddle sold 26,760 acres at £2 7s. 6d. an acre in 1905, and this was cut up for closer settlement in blocks of about 700 to 800 acres, and records show that the total number was 49 blocks. To-day there are only 11 original settlers left.

THE EXPERIMENTAL FARM.

The homestead, together with 1,005 acres immediately surrounding it, was retained for an experimental farm, in order to assist the new settlers and the South-East generally. Two blocks were not allotted, and these were also used for same by the farm.

LAND.

The land is slightly undulating, and varies considerably in texture, color, and composition. However, the greater portion consists of a comparatively heavy, cementy loam, containing a large proportion of ironstone rubble over a very stiff clay, which varies in depth, and is practically deficient in lime. There is, however, a fair amount of heavy "crab-hole" land, which is more fertile, but also more difficult to work. Land of a similar type is to be found alongside the Victorian border practically to the coast.

NATURAL VEGETATION.

The natural timber consisted of fine, stately red and blue gums, with some magnificent and not sufficiently appreciated, but shady and shapely dry land ~~ti-trees~~ and bulloaks; these trees present a fine, park-like appearance, and have a

charm all of their own. Mr. Ebenezer Ward, in his book, "The South-Eastern District, 1869," states that "Although ordinary good grazing land, I am doubtful whether much of it could be profitably farmed."

The natural grasses were mainly wallaby grass, silver grass, and kangaroo grass, but since much of it was rather wet during the winter, it grew very little useful vegetation naturally, as we shall see later on. Then, large'y on account of the ill-nourished sheep, it was known by some as "Scabybolite."

NATURAL DRAINAGE.

Throughout this district, a number of runaway holes are found. These consist of depressions into which the water gradually flows and then gradually disappears, nobody knows quite where. These holes are both interesting and useful, and enormous quantities of water disappear down them in a very short time, and the change in appearance overnight is nearly enough to make one wonder if they can believe their eyes.

One of the holes is situated in part of the homestead at Kybybolite. The old station garden was planted on the banks surrounding this runaway hole, and was quite a source of attraction in the early days, particularly when the fruit was ripe. Kybybolite is a native name, and some say that it means "runaway hole," or "the noise that the water makes running down these holes." In the early days during the winter months it was difficult, and even dangerous, to gallop a horse over much of this country because it was so soft that a horse would sink to his knees, and teams would get bogged when drawing empty vehicles.

Under these conditions the difficulty of growing cereal crops can be better imagined than described, and thus the earlier managers spent considerable time and money in the making of drains to receive the surplus water, three-quarters of which they were able to drain into the runaway hole previously mentioned, and the remainder into one of the branches of the Naracoorte Creek.

A few figures relating to the rainfall may be interesting here, at the same time showing the disabilities which the earlier settlers had to contend with. The rainfall for the year ended December 31st, 1906, was 36in., of which 4in. fell during May, 5.35in. in June, and 9.35in. in July; then in 1909 the total fall was 27.84in.; 1910, 28.35in.; 1917, 26.69in.; and 1923, 25.67in.; since then the annual fall has been lighter.

The average yearly fall, 1906 to 1930, is 21.85in., whilst the average for 1906-1912 was 25.63in., then 1906-1915, 23.31in., and 1916-1925, 21.04in., and 1926-1930, 20.6in. The need for drainage was apparent since the growing of cereals was the main objective, and therefore 19 miles of surface drains were excavated by means of a plough and crowder, at an estimated cost of £2 per mile. The remains of many of these can still be seen to-day, but of latter years they have hardly functioned. Then later, in some of the fields difficult to drain, the land was ploughed in lands with a high crown to facilitate drainage.

MANAGERS.

The first manager, Mr. Simein Schinckel, of Naracoorte, was appointed in because of his practical knowledge of local conditions. He held the position for 12 months, and did a good deal of pioneering work under Professor Angus. Then he handed over to Mr. Harold Wilson, now manager of Werribee Research Farm, Victoria. He was transferred to Loxton Experimental Farm in 1909, when Mr. W. J. Colbatch was appointed Superintendent of Agriculture in the South-East, and stationed at Kybybolite. His efforts were mainly spent in getting a good grip of the conditions, and some years the yields for wheat were as high as 27bush. per acre. Then, in other years, they were as low as 6bush. per acre, and therefore it can be readily understood that he was soon convinced that cereal growing could not be carried on without drainage. He therefore turned his attention to this problem,

and also the testing of various grasses, in addition to such pioneering work as clearing, ring-barking, and burning logs, &c. Some fields were cleared by means of explosives, and some local residents have a vivid recollection of some of the demonstrations.

Whilst Mr. W. J. Colebatch was in charge he had the boundary of the farm securely wire-netted, thus making it rabbit-proof, and at the same time many fields were subdivided and made into smaller and more useful paddocks; many of the roads were formed, bores put down, windmills and tanks erected, and the cypress planted either side of the drive from the siding to the homestead. The men's quarters and the implement shed were also built.

POULTRY.

A poultry station was carried on under the supervision of Mr. D. F. Laurie, with Mr. W. C. Kearney in charge, and an egg-laying competition was conducted for the benefit of the South-Eastern poultry keepers.

Then Mr. L. S. Davis took charge for a year or two under Professor A. J. Perkins, Director of Agriculture. He inaugurated the change-over to livestock from cereals. The present manager, Mr. L. J. Cook, took charge in 1920, and he has raised the standard of work to a very high degree. It was largely owing to his efforts that the experimental farm was not closed a few years ago. When Mr Cook took charge, all the young stock had to be sent away, as soon as they were weaned, to another farm, Veitch, in the Murray Mallee. But now, with the use of licks and top-dressing and improvement of pastures, this difficulty has been overcome, and during the last year or so the position has been reversed, and they have stock from other farms on agistments.

STOCK RECORDS.

When the estate was cut up in 1906 it was subdivided into holdings of about 700 to 800 acres each; records show that the total number was 49 blocks. The homestead, together with 1,005 acres immediately around it, was retained for an experimental farm, in order to assist the new settlers and the South-East generally. However, two other blocks were unallotted, and they were also used until 1920.

In 1910 the total area of the farm was 2,272 acres. Area under crop was 432 acres; fallow, 69 acres; orchard, 12 acres; roads, yards, &c., 10 acres; natural grasses, 1,749 acres. Stock consisted of 23 horses, 21 cattle, 19 pigs, and 1,302 sheep.

To-day the area of the farm is made up as follows:—Under crop, 148 acres; pastures 797 acres (including 100 acres not improved); road, yards, orchards, etc., 60 acres. The stock carried for the immediate 12 months were as follows:—Horses, 24 (including 20 on agistment); cattle, 122; pigs, 58; sheep, 1,464 (including stud English Leicester and Crossbred breeding ewes).

Mr. Cook, in his 1930 report, stated that the number of sheep carried on the farm has increased 148 per cent., and 224 per cent. in production of wool during the last six years.

Then in 1931 his report shows a further increase over the seven-year period:—Number of sheep increased 150 per cent., and wool 200 per cent., and the cattle 98 per cent., and butterfat 152 per cent.

Thirty years ago 26,760 acres cut 200 bales of wool, or it took 130 acres to produce one bale of wool; to-day 1,000 acres are producing 90 bales, or one bale from 11 acres. It has been estimated that to-day there are 33,000 sheep, 700 cattle, and 150 horses running on what was the Kybybolite Estate. Of this area about 9,000 acres have been improved, and the balance is just as it was in station days, except some which has been broken up and cropped, and then left without further treatment, and probably of the 9,000 acres not more than half is regularly top-dressed.

LEVELLING.

A considerable area of the land in this district is somewhat similar to many other parts of the Commonwealth; the surface is so irregular that it needs levelling before it can be cultivated satisfactorily. Those areas enjoy several names, as "Bay of Biscay," or "Crab-hole," or "Gilgi," which give some idea of their natural appearance, which someone has described thus—"It looks as though someone had used a tip-dray all over it." The holes vary in depth from a few inches to over a foot, and from 3ft. to 2 chains wide. Mr. Colebatch commenced by using a plough and scoop for filling the larger holes. Then later Mr. Syd. Shepherd made a leveller, which he used with success on his farm. The land was first ploughed when wet with a disc plough, then left until harvest, when the leveller was used. A paddock of 200 acres, which grew practically nothing, was thus converted into one of his best paddocks, and he is now using it on his other fields, levelling them, and thereby making his holding more valuable and productive, for levelling prevents the surplus water from lying about, and improves the conditions for stock generally, especially lambing ewes.

GRASS OR MEADOW HAY.

The increased stock-carrying conditions which were brought about with the improved pastures necessitated the storing of some of this vegetation for use during the lean periods of the year. Mr. L. J. Cook, Manager of Kybybolite Experimental Farm, saw the need for this, and arranged a Field Day, when a number of implements were given a trial on one of the farm paddocks. The result was so successful that now each year the majority of the settlers cut some of their surplus feed during the spring, and store as either ensilage or meadow hay.

The clover and grass is first cut with a grass mower, then picked up with a sweep rake, and conveyed either to the stack or, in the case of hay, it may be pushed up to the baling or pressing machine, and put into handy-sized bales.

Where the loose stuff is stacked, stackers are used. These save the heavy labor involved in pitching it up on to the stacks. This is a big consideration, because the difficulty of handling loose hay was one of the principal reasons that more of this class of fodder was not used. Then last year a grab was introduced for handling the ensilage and hay, and this implement will be generally used.

Another difficulty was the cutting of these heavy crops of clover in the early days, but to-day by using machines with shorter cutting blades and a faster drive, no difficulty is experienced in handling the heaviest and most tangled crops. At the present time five baling plants are in regular use in the Kybybolite district.

DEPARTMENT OF AGRICULTURE.

Bulls that are purchased under regulations of the Dairy Cattle Improvement Act, and upon which Government pays a subsidy, are available, for two years after purchase, to serve a certain number of outside cows.

The following list, compiled by the Department of Agriculture, shows the names of such bulls and of the people who own them, and indicates also the months until which the respective owners will be prepared to make the services available.

As will be noticed, the distribution of subsidised bulls is now fairly general throughout the State; hence, many of those persons, who in the past have found it difficult to get the use of a good bull, should not have much similar trouble in the future. And here let it be stated that everyone of these subsidised animals is a registered pure-bred and from a dam of proved productivity under Government official test.

The maximum service fee is 10s. per cow.

For the information of cowkeepers, it is pointed out that, although the addresses as given in the following list are those to which application should be made for the services of the bulls, the bulls themselves may, in a few instances, be located elsewhere.

THE WINNING ENTRY.

In his comments on the various entries, Mr. Hill stated that the stack entered by the winner was exceptionally well cured and well housed in an iron-roofed hayshed. It consisted of a mixture of subterranean clover, barley grass, soft brome grass, sterile brome, silver grass, perennial rye grass, and a little geranium. It was of splendid colour with the clover leaves all intact, and the whole mixture handled well. Top-dressed with two cwts. of super per acre, and the hay was cut when the clover was in the flowering stage; left in rows and carted within ten days of cutting. It was a very attractive hay, and the herd of cows was keeping up production without the addition of concentrates.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF MID-NORTHERN BRANCHES.

The Annual Conference of Branches of the Agricultural Bureau was held at Laura on March 14th.

Mr. R. H. Lines presided, and the opening address was delivered by the Hon. A. P. Blessing, M.L.C. Messrs. W. J. Spafford (Deputy Director of Agriculture), Dr. A. R. Callaghan (Principal Roseworthy Agricultural College), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), E. L. Orchard and J. O. Hatter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary) represented the Department of Agriculture.

The following papers were read and discussed:—"Bush Fire Legislation," R. J. Rose (Laura); "Growing and Harvesting Lucerne Seed," K. H. Moore (James-town); "Increasing the Sheep carried on the Small Farm," W. J. Cronin (North Bundaleer); "Refrigeration," J. Bowker (Laura).

Addresses were delivered by Messrs. W. J. Spafford, "Diseases of Cereals," and "Pigs on the Farm," by H. B. Barlow.

Conference adopted the following resolutions:—"That the 1935 Conference be held at Redhill;" "That section 17 of the Bush Fires Act be altered to compel all farmers to clear and plough around their own crops;" "That a travelling veterinary surgeon be appointed to visit all districts of the State;" "That flour millers be requested to put flour into new bags;" "That in the opinion of this Conference district councils should more rigidly enforce the provisions of the Noxious Weeds Act;" "That the Government be requested to raise the price of wheat."

At the evening session Mr. Anderson delivered an address, illustrated with lantern slides, "Poultry on the Farm."

WOMEN'S SESSION.

A special session was held for delegates from Women's Branches in the Mid-North Districts. The following papers were read:—"Feeding of Infants," Sister Harslett (Gladstone); "Good Fellowship," Mrs. F. Cummings (Belalie); "Toys," Mrs. S. Page (Belalie). Miss E. Campbell, of the Education Department, addressed the delegates.

CONFERENCE OF LOWER SOUTH-EASTERN BRANCHES.

The Committee of the Tantanoola Branch of the Agricultural Bureau is to be congratulated on the very fine attendance of representatives of Branches in the Lower South-East who attended the Annual Conference at Tantanoola on April 11th. Delegates were present from the following Branches:—Allandale East, Penola, Mount Gambier, Millicent, Rendelsham, Kalangadoo, and Tantanoola.

Mr. G. H. Bird (Chairman of the local Branch) presided, and the Department of Agriculture was represented by Messrs. W. J. Spafford (Deputy Director of Agriculture), who delivered the opening address, H. B. Barlow (Chief Dairy Instructor), L. J. Cook (Manager, Kybybolite Experimental Farm), E. S. Alcock, W. H. Downes, and A. L. Warren (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary of the Agricultural Bureau).

The agenda covered a wide range of subjects, the following papers providing excellent discussions:—"Sore Shoulders on Horses," J. Carthew (Tantanoola); "Motor Taxation from the Point of View of Primary Producers," W. M. Laslett (Allandale East); "Improving the Butter Fat Standard of Dairy Herds," W. H. Downes (Mount Gambier); "Side Lines on the Farm," R. Hateley (Millicent); "Is Mixed Farming Scientifically or Economically Unsound?" A. A. Sassanowsky (Mount Gambier).

Conference adopted the following resolutions:—"That the 1935 Conference be held at Mount Gambier." "That this Conference strongly recommends that arrangements be made for a deputation, comprising delegates from all Branches of the Bureau, to

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)	
F. COLEMAN, J.P.	A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc.	PROF. A. J. PERKINS
D. A. LYALL, ESQ.	W. J. ADEY, ESQ.
H. C. PRITCHARD, A.F.I.A. (SECRETARY)	

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,

Agricultural College,

ROSEWORTHY.

wait on the Premier during the next Annual Congress requesting either the abolition or a substantial reduction in motor registration, and that the resolution be included on the 1934 Congress agenda." "That this Conference appreciates the action of the Commonwealth Government in granting a rebate on super, and strongly recommends the continuance of the scheme." "That the income tax returns papers be made less complicated—more like the old income tax papers."

CONFERENCE OF UPPER SOUTH-EASTERN BRANCHES.

Branches represented in the Upper South-East held their Annual Conference at Wolseley on March 21st.

Mr. J. E. Ridgway, president of the Wolseley Branch, occupied the chair, and the opening address was delivered by Mr. S. Shepherd, member of the Advisory Board of Agriculture. Messrs. W. J. Spafford (Deputy Director of Agriculture), C. F. Anderson (Poultry Expert), A. L. Warren (District Horticultural Instructor), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary) of the Agricultural Bureau, attended on behalf of the Department of Agriculture.

Papers were read by Messrs. G. D. Butler (Wolseley), "Fallowing," and H. Bond (Tatiara), "Malting Barley."

Mr. Spafford replied to questions dealing with various aspects of the cultivation of wheat, and addressed delegates on "Fat Lambs." Mr. Anderson also delivered an address, "The Poultry Industry."

It was decided that the 1935 Conference should be held at Mundalla, and that a veterinary officer should be attached to the Agricultural Bureau, quite apart from the Stock and Brands Department, this matter to be treated as very urgent.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on March 28th, there being present Messrs. A. J. Cooke (Chairman), S. Shepherd, P. J. Baily, F. Coleman, H. N. Wicks, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary).

Apologies were received from Messrs. R. H. Martin, A. M. Dawkins, and Prof. A. J. Perkins.

Resignation of Member.—The resignation of Mr. P. H. Jones was accepted, and it was decided to place on record an appreciation of his services to the Agricultural Bureau of South Australia.

Appointment of New Member.—The Secretary reported that Mr. A. J. A. Koch had accepted the invitation of the Minister to act as a member of the Board.

Broadcasting Lectures.—The Secretary reported that a series of six broadcast addresses had been arranged by departmental officers, which would be given at fortnightly intervals, and that if proved satisfactory arrangements to be made for a further series.

Life Members.—Messrs. E. R. Moss and E. J. Moritz were approved as life members of the Agricultural Bureau.

New Members.—The following names were added to the rolls of existing Branches.—Gladstone Women's—Miss T. Leesue; Wandearah—T. Ryan, H. Davis, A. L. O'Shaughnessy, J. Dennis, E. V. Eagle, W. Vanstone, R. Vanstone, M. Coventry; Balhannah Women's—Mrs. R. James; Allandale East—T. A. Earl; Snowtown—G. T. Freebairn; Blyth—E. H. Denning; Myponga—D. Coombe; Laura—J. L. Read, L. S. Wurm, E. T. Hollitt; Auburn Women's—Miss Hitchcox; Sutherlands—E. Bannear; Brownlow—B. Biar; Warrambo—Albert Hurrell; Upper Wakefield—H. W. Gregor, E. C. Gregor; Nantawarra—M. P. Hamdorf; Truro—A. J. Steinert, O. C. Steinert; Cummins—W. L. Reed; Yaninee—J. G. Christian, C. H. Ruhe, J. Michell, W. J. Wilkins, C. C. Chewings, C. Kidman, J. Holland, C. A. Roe.

No. of present members, 8,024; No. of Branches, 336.

Several items were discussed in Committee.

RAINFALL TABLE.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

MEN'S BRANCHES. SOUTH-EASTERN DISTRICT.

PENOLA (Average annual rainfall, 26.06in.).

March 10th.—Attendance, 11.

The meeting took the form of a debate, "Specialised *versus* Mixed Farming." The Rev. McNaughton acted as adjudicator. Mr. Provis, as leader, with Messrs. J. Harmer and E. R. D. Hinze spoke in favor of mixed farming, and Mr. W. A. Clifford, as leader, with Messrs. E. Kidman and Mr. S. Ockley as supporters of specialised farming. The adjudicator awarded Mr. Clifford's team 86 points, and Mr. Provis's team 85 points. (Secretary, F. Hinze.)

WEPOWIE (Average annual rainfall, 12.46in.).

October 2nd.—Attendance, 10.

HAY MAKING.—Paper read by Mr. L. R. Jasper.—"The best time to cut wheaten hay is when the grain is in the milky stage—about 12 days after flowering. Oats should not be cut before the straw shows purple at the bottom. If the hay is cut at this period stock will eat more readily. When the hay is cut it should be left 24 hours before stooking, if the ground is dry when stooking. I prefer the lying down stook; the sheaves are pressed down flat, which makes them better for handling, and they retain their weight better than those standing upright. If weather conditions are favorable, hay can be stacked 14 days after cutting. Build square corners in preference to a stack with round ends, because there is not so much danger of the ends slipping,

and they are more easily covered with straw, having only the two sides to cover. Always build with the butts outwards before starting to roof, fill the centre about 4ft. above the walls, giving the sheaves a good slope upwards.'¹

HARVEST REPORTS.—Meeting held February 12th.—Present: 12 members.—Mr. W. Rooke reported 9 bags to the acre on fallow from Early Burt and Palestine oats. Rane and Turvey yielded 14bush. each; Nabawa, Sultan, and Waratah each 9 bush. Stubble ground—Rane, Nabawa, and Joffre 4bush. Mr. C. Knauerhase sowed chiefly Rane, which yielded best on the late and roughest fallow, namely, 12bush. Mr. G. Gregurke: Waratah, 9½bush. and 14½bush.; Felix, 12bush.; Curly's Early, 19bush.; Rane and Werribee, 9½bush.—this field was struck by a hailstorm in October. Early Burt oats yielded 9½ bags to the acre. Mr. J. Burns: Nabawa, 21bush.; Rane, 15bush.; Waratah, 12bush.; Werribee, 10bush.; Rane on ground that had not been worked for 15 years, 6 bush. New ground (first crop) 12bush., old ground under same sowing 10bush. (Rane). Farm average, 11½bush. Mr. J. Crocker: Rane on best fallow yielded 18bush.; Rane on late fallow 8bush.; King's White, 10½bush.; Federation, Nabawa, and Rane, 8½bush. on stubble. Mr. L. Jasper: Rane, 14bush. after severe hailstorm in October; Turvey, 10bush.; and Nabawa, 9bush. Farm average, 12bush. Mr. T. Orrock sowed chiefly Rane 4H., which averaged 15bush.; Nabawa and Noonga each yielded 12bush.; Rane 4H. was procured from Dookie College in Victoria two years ago. Two bags have this year, in its second sowing, produced over 1,000 bags, and has been distributed on 34 farms this season to the extent of 700 bags. Mr. E. Rooke: 16½bush. from Canberra, Waratah, and Rane. Nabawa was rather disappointing, only yielding 14bush., yet looked the pick of the farm; unfavorable weather being the chief factor in the ripening stage. Early Burt and Palestine oats, 6 bags. (Secretary, E. Rooke.)

Other Reports Received.

Wilmington	13/3/34	19	Address—H. B. Barlow .	C. Cole

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

MURRAYTOWN.

February 24th.—Attendance, 8.

HARVEST REPORTS.—Members reported as follows:—Mr. F. Borgas sowed 60lbs. seed, 60lbs. super—Currawa, good heavy grain, 24bush.; Penny, 24bush.; Nabawa (pinched), 24bush.; Rane, 21bush. good grain; Rane on stubble, 15bush.. Messrs. N. and A. Scholz (14in. rain for year) sowed 60lbs. super, 60lbs. wheat—Currawa and Free Gallipoli, 27bush.; Rane, 8 to 9 bags, on stubble 5 bags. Mr. W. Scholz—Sword, thin crop, good grain, 30bush.; Free Gallipoli, 8 to 9 bags, cracked badly when harvested; Currawa, 8 bags; Rane, to 9 bags. Mr. E. Bonham—good crop of Rane, Federation, and Ford. Mr. E. B. Pitman sowed 60lbs. super and 60lbs. wheat—Free Gallipoli, 30bush.; Rane, 21bush. to 42bush. (300 acres); Sword, 24bush.; Marshall's No. 3 and Lens, 30bush. each; Early Burt oats, 45bush. (Secretary, E. Pitman.)

LOWER-NORTH DISTRICT.**(ADELAIDE TO FARRELL'S FLAT.)****LONE PINE.****January Meeting.**

HARVEST REPORTS by Mr. J. Christian.—“The harvest in this district has been satisfactory with the exception of some crop which had to be sown late on account of the land being infested with sour-sobs, and were then too far backward when the warm weather and hot winds set in at the end of September. Hardly any damage to the crop was caused by frost. The weather for hay cutting was good with the exception of a few very hot days, but later for stripping the weather was rather unsuitable, being cool and windy. Some of the early sown crops on good fallow which were fed off with sheep yielded exceptionally well. Mr. C. F. Beckmann's Le Hugenot yielded 12 bags per acre, and Mr. F. Schulz's Waratah also averaged 12 bags, with Mr. Nettelböck's yielding 11 bags. Mr. J. Neldner's Le Hugenot went 10 bags, but was not fed off by sheep, and Nabawa averaged 9 bags. My crop of Sepoy and Teakle on red gravelly and hard setting soil was a very thin crop, but had a very plump grain and yielded 5 bags per acre. Mr. E. R. Hentschke averaged 6 and 8 bags of Sepoy and Teakle on good fallow. Some very good returns were also received from Sword, Correll's, and Ford. The best yield was from Sword by Mr. F. Fromm on late fallow, while Correll's and Ford had given the best straw though the lowest yield. Cape barley was sown late, yielded 8 bags, and the earlier sown yielded 10 bags. Algerian Cape oats yielded 10 bags, and the oats cut for hay went 1½ tons per acre. Mr. E. Alm cut 2 tons of hay per acre. Some of Mr. J. Neldner's and C. F. Beckmann's went over 2 tons per acre, sown in about the beginning of May at the rate of about 1½bush. to 2bush. of seed and 1cwt. of super per acre. The pea crop was very light, being damaged partly by the dry spring and hot winds and also by frost. The best yield was 7 bags, some only yielded 3 bags to the acre, being only half the crop of last year.” (Secretary, S. Turnbull.)

YORKE PENINSULA DISTRICT.

ARTHURTON (Average annual rainfall, 16in. to 17in.).

February 15th.—Attendance, 14.

HARVEST REPORTS.—Mr. W. Bagshaw reported Ghurka and Sword over 30bush. per acre. Mr. S. Coleman said wheat crops had yielded far better than had been expected, Ford returning over 12 bags per acre. Other varieties had returned over 10 bags per acre. The splendid yield would be some compensation for the very low price offering for wheat. In barley Mr. S. Coleman said his return had been 8 bags per acre on stubble land and 12 on grass land. Mr. M. Hynes had received best results from Ford, Caliph, and Nabawa. Mr. P. Roads said Dan and Ghurka had returned 11 bags per acre. Mr. L. Clasohm had not found much difference in varieties of wheat, but gave preference to Sword. Grass land had yielded 12 bags per acre. Mr. O. Jericho said Waratah had not given good results with him; other varieties returned over 30bush. per acre. Barley had yielded well. Mr. E. Clasohm's average was about 11 bags per acre. Mr. S. Henderson reported an average of 33bush. of wheat and 22bush. of barley. A paddock of wheat that he had entered for crop competitions yielded 39bush. per acre. Members all agreed that wheat at present prices would not pay expenses. Barley had been of great assistance to local farmers.

A further meeting was held on March 1st at Mr. T. Rodda's residence, there being present 14 members and visitors from the Boor's Plains Branch. Papers were read from the original minute book of the Branch, reporting meetings held 43 years ago. (Secretary, T. Howlett.)

BRENTWOOD (Average annual rainfall, 15.45in.).

February 8th.—Attendance, 12.

HARVEST REPORT.—Mr. J. Honner, after giving a resume of the weather, gave the following report:—"The past season proved once again the wonderful stamina of the wheat plant on Yorke Peninsula, for crops yielded from 15bush. to 36bush. to the acre on some of the best farms, with an average of 21bush. for this district. The sample in most cases was excellent, and crops practically free from disease in every particular. Good fallow proved its value other than where seeded too early, for it appears undesirable to start seeding until seven or nine days after a soaking rain. The most successful varieties of wheat were Ford and Sword, with good crops of Ranee, Major, Nabawa, Waratah, and Ghurka. The early harvesting period of the season was broken with cool weather generally, which resulted in less skinned barley and spread the delivery period over the whole harvesting.

The price of wheat was disappointing, opening at 2s. 3d. and ranging between that price and 2s. The prospect of any substantial rise is remote, with only Great Britain a buyer and all other nations—once customers of Australia—now self-supporting, and either sellers or indifferent buyers.

Barley crops were of a mixed quality owing to the adverse weather conditions of October. Nevertheless quite half of the harvest appealed to buyers, and owing to scarce supplies of malt on hand, fully two-thirds of the harvest was purchased at 2s. to 2s. 3½d., leaving a lesser portion to be pooled than is usual. Although the yield of barley was light—say, 15bush. to the acre average—again there was an absence of diseased and damaged or skinned grain. There is a tendency for farmers to grow more Californian Cape, which appears to meet a steady market at 2s. 2d. to 2s. 3d. per bushel, and merchants say there is an unlimited demand for quality Cape in England. Our experience with Californian Cape is that it yields well and ripens a fortnight later than Prior, thus minimising the risk of having a lot of barley ripe at the one time. Farmers could do worse than combine the two varieties. Yields up to 20 bags per acre were reported.

The quantities of grain delivered at Minlacowie would be in the vicinity of wheat 60,00 bags and barley 75,000 bags. Oats are grown chiefly for hay, and this year the yield per acre was approximately 30cwts. to the acre. The much talked of super and sulphate of ammonia mixture for barley and wheat on stubble land did not come up to expectations. There certainly was a difference, but the cost is too great to get the increased yield. With every prospect of low prices, quality and not quantity should be our motto for the coming year."

PASKEVILLE (Average annual rainfall, 15.52in.).

February 27th.—Attendance, 8.

HARVEST REPORTS.—Satisfactory yields were reported. Among the best yielding varieties were Waratah first, then Sword, Ranee, and Ford in that order. Samples in some instances were pinched, and the prevalence of barley was again noticeable. There were very few cases of smut. Generally speaking, the sample was considered very good. (Secretary, J. Prouse.)

WEAVERS (Average annual rainfall, 16.84in.).

February 5th.—Attendance, 11.

HARVEST REPORTS.—Mr. J. Bridges spoke on the harvest from a buyer's point of view, and said the wheat delivered was the best quality that had been grown for a number of years. Barley this year compared favorably with the best last year, but the poor quality was very inferior. Mr. W. Agnew said Ford yielded much better than Nabawa. Mr. W. Anderson reported Waratah as his best crop, with Sword second and Ford and Ranee third. Barley suffered badly for the want of a little more rain in the growing period. Mr. L. Slade said barley that was frosted just as it was coming through the ground was sure to be affected in the yield, but the sample was generally good. All wheat should be graded before being sown to remove all small seeds and cracked grain. He had reaped a splendid crop of Sword where 2,000 sheep had been grazing for some time to eat Sand Rocket. (Secretary, H. Cornish.)

WESTERN DISTRICT.**WARRAMBOO.**

February 13th.—Attendance, 11.

HARVEST REPORTS.—Mr. P. Daniel reported late sown crops badly pinched, but they weighed heavier than early sown, which was not pinched so bad. Late sown yielded 8bush., early a little better. Mr. J. Sampson had an 8bush. average, fallow 12bush. Golden Drop and Gluyas were his best wheats. Mr. O. Murphy: Fallow 12bush, farm average 10bush., Waratah was the best crop on new ground, going 10bush. Mr. A. Collins reported mid-season wheat more affected with take-all and hay-die. Mr. F. Chilman: Nabawa badly affected with hay-die, Gluyas on fallow 12bush. (Secretary, F. Chilman.)

EASTERN DISTRICT.**OVERLAND CORNER** (Average annual rainfall, 10.37in.).

February 9th.—Attendance, 12.

HARVEST REPORTS.—The subject for the evening was "Harvest Reports." The chairman in his report showed conclusively that nothing but fallow paid, stubble ground was a complete failure, while fair returns were obtained off the fallow ground. Mr. G. Chesney reported the same experience. Mr. T. Atkinson, who had the outstanding crop of the district, gave a very interesting account of his year's experience, with the aid of the blackboard. He experimented with new land by fallowing it. He also put in new land straight after the burn off. The result was up to 12bush. per acre off new land fallow, 3bush. per acre off new land. The new land was put in with same wheat and quantity of super and at the same time as the fallow. Not only would the difference be in wheat yield, but a clean stubble burn would result, destroying shoots, etc., whereas the new land was a wilderness of shoots, and a burn impossible; a big factor in working costs and condition of the land. His experience was a complete demonstration of the fact that it paid to fallow new land in the mallee. The crop results were obtained with a 3½in. rainfall during the growing period. Mr. Atkinson also reported having sown ½lb. of Wimmera rye grass to the acre, with wheat, on new country, and believed a fair seeding for next year would result. The rye grass was put in the dry pickler with the wheat, and an even distribution was obtained. He recommended farmers to sow rye grass on new country and get it established before other weeds appeared. (Secretary, Len. Atkinson.)

SOUTH AND HILLS DISTRICT.**FRAYVILLE.**

March 1st.—Attendance, 10.

HARVEST REPORTS.—Harvest reports were given by each member present. Among the leading varieties of wheats mentioned were Free Gallipoli, Rancee, Sword, and Nabawa. Currawa was generally condemned owing to its uncertainty. Members discussed the use of a roller for pulling out chokes of harvesting machinery. One member said he reaped a comparatively difficult crop of Nabawa with its use, thereby saving the heavy expense of buying a reaper-thresher. (Secretary, H. Ramm.)

McLAREN FLAT BUREAU FIELD DAY.

In company with Messrs. R. Fowler, H. H. Orchard, and F. C. Richards, of the Department of Agriculture, members of the McLaren Flat Branch of the Agricultural Bureau, including Mr. G. Connor, M.P., inspected a number of orchards in the McLaren

Flat District on Saturday, March 17th. After lunch, which was provided by the members of the Local Women's Branch of the Bureau, the party moved on to Mr. W. L. Townsend's orchard and vineyard. His property consists of 50 acres planted

McLaren Flat Field Day Those who took part in the Tour of Inspection

with currants, wine grapes, apples, and prunes, and the main crops are currants and prunes, of which he harvests each year 14 and 2 tons respectively. Evidence of the lack of rain was noticed in practically every orchard. Mr. Townsend said where the

Annual Field Day, Blackwood Agricultural Bureau.

soil has been well cultivated the vines were standing up to the dry conditions, but where this work had been neglected, the vines were suffering. Under the guidance of Mr. Townsend, the party next visited Mrs. Lowe's house, to visit what local residents

claim to be one of the oldest vines in tthe State. The girth of the butt of this vine 18in. from the ground is 4ft. 10in., and the vine is trellised all around the house, a distance of 126ft. One year over 1 ton of grapes was picked off this vine. The age of this vine can be vouched for by Mrs. Lydiard, who now resides at McLaren Vale. She is 90 years old, and has distinct recollection of the vine when she was a young girl.

Perhaps one of the most interesting places that the party visited was that of Mr. R. G. Bell. The sheds, drying racks, and all outbuildings were in excellent order. Mr. Bell has one of the most up-to-date plants in South Australia for the cleaning and packing of dried fruits. Boxes for the fruit are made on the premises; 240 tons of currants are packed each year for export. Mr. Bell has installed a dehydrator. Twenty-four hours after the fruit has been taken off the tree and passed through a dehydrator it is ready for packing. Its capacity is 3,600lb. of prunes and just under 2 tons of currants. In bad weather, Mr. Bell said he had worked the machine three weeks, day and night, without stopping. It is electrically driven, the power costing 3s. 6d. for 24 hours.

WOMEN'S BRANCHES.

THE FOOD VALUE OF MILK.

NUTRITIVE VALUE OF THE SEVERAL COMPONENTS OF MILK.

[Continued from page 1056.]

THE PROTEINS.

Milk contains the proteins casein, lactalbumin, lactoglobulin, and an alcohol soluble protein. These supply about 19 per cent. of the total calories of milk. The principal protein, casein, best known perhaps in the form of cottage cheese, is characterised by containing 0.8 to 0.9 per cent. phosphorus. It is present in cow's milk to the extent of 3 to 4 per cent. and in human milk in a decidedly smaller amount—0.05 to 1.5 per cent.

Lactalbumin, the principal protein of whey, or milk serum, is present as 0.5 per cent. of whole cow's milk and represents about one-sixth of the total protein. Human milk contains a greater proportion of lactalbumin than does cow's milk. The lactalbumin content of cow's milk is equivalent to one-tenth of the casein, whereas in human milk it is equivalent to one-fifth of the casein.

These two proteins, comprising about 93 per cent. of the total milk proteins, are both biologically complete, that is, either one given in sufficient quantity has been found to support satisfactory growth and reproduction in suitable test animals, provided the protein is fed in conjunction with an otherwise adequate diet.

Of particular interest are the experiments which demonstrate that the nitrogen of milk is more efficiently utilised by the human body than is the nitrogen of various other foods.

The proteins of milk are equally readily assimilated whether presented in the form of whole milk, evaporated milk, dried milk, cheese, or purified casein. Infants appear to utilise the protein from heat-treated milk rather more readily than that from untreated milk, since in the former case undigested protein curds do not appear in the stools.

THE CARBOHYDRATES.

Lactose, on digestion, is split into glucose and galactose. It is non-fermentable by ordinary baker's yeast. Lactose possesses slight laxative properties.

Liberal quantities of this carbohydrate in the diet produce a favorable medium in the intestine for the growth of the non-putrefactive organisms.

Lactose plays a peculiar role in the diet inasmuch as it increases, in some unexplained manner, the absorption of the salts of calcium, or phosphorus, or both, from the gut, and their retention in the animal body. Under certain conditions the influence of this sugar in inducing proper deposition of inorganic salts into the bones may be as great as that of the bone-calcifying vitamin D. In this connection it should be pointed out that the incidence and severity of rickets is much less in babies reared on human milk than on cow's milk in spite of the richer supply of inorganic salts in the latter milk. This may be associated with the higher lactose content of human milk.

THE FAT.

Milk fat is easily digestible. Owing to its fine emulsification in milk a considerable portion may undergo digestion in the stomach. The size of the fat globules is a species characteristic. The fat globules of human milk and goat's milk are relatively smaller in diameter than are those in the milk of the cow, and are consequently more easily digested by the enzymes of the gastro-intestinal tract.

From a nutritional point of view, butterfat is notably valuable as a source of the fat-soluble vitamins. There is also a growing belief that fat, or rather certain fatty acids, are necessary adjuncts to a normal diet.

THE INORGANIC SALTS.

The inorganic salts or ash constituents comprise the residue that remains when all the organic matter in the food is burned away by heating in the presence of air; they supply an essential part of the diet. Numerous substances of this type are necessary for the growth of the skeleton, for the development of the soft tissues of the body, and for the maintenance of the osmotic pressure and of the neutrality of the body fluids. These substances are more satisfactorily supplied by milk than by any other feasible combination of natural foods. During the early period of infancy, when the rate of growth is so phenomenally rapid, milk is the major source of the inorganic substances in the diet of most mammals, and at this time the demand for these substances is great, owing to the enormous growth in size of the skeleton.

Iron and copper are the only known essential elements that occur in milk in less than optimal quantities; although only small quantities are required, red blood cells cannot be formed by the body unless these metals are supplied. Young animals at birth, however, possess a goodly supply of both these elements, and this tides them over until a mixed diet can be given. When the supply of iron and copper in the body is exhausted, normal growth ceases and anaemia may result. Restoration to normal growth and health by the addition of other foods will occur only in so far as these contain iron and copper.

The calcium content of cow's milk is three times that of wheat and six times that of corn. Milk is the best source of dietary calcium; all other foods, with the exception of the green leafy vegetables, are relatively poor sources of this substance. Calcium retention by the animal body, furthermore, is greater when milk is fed than if the same amount of calcium were given in the form of vegetables. Babies reared on cow's milk absorb and retain more calcium and phosphorus than do those reared on human milk. Experiments on children between the ages of 3 and 13 years have demonstrated that optimum storage of calcium is made when the daily diet of the child contains at least 1 quart of milk.

The inorganic constituents of milk vary according to the stage of lactation, the season and the locality in which the milk is produced. Data reported for the iodine content in two sections of the United States are of particular interest. Cows in a dairy section of New York produced in the summer a milk which, in a dry powdered form, contained 145 parts of iodine per billion; during the winter months the iodine fell to 67 parts per billion. Milk powder from Wisconsin, however, contained 704 parts of iodine per billion in the summer and 961 in the winter.

Dried and evaporated milks may contain more iron and copper than the original fluid milk. Milks desiccated by the revolving cylinder process have been reported to contain two to five times more iron than the original milk owing to the dissolution of iron from the metallic cylinders. The copper vacuum pans and tubes used in the commercial evaporation of milk may also increase the copper content of the milk. Milks dried by the spray process do not contain additional iron.

Pasteurisation, boiling, or evaporation may cause a slight precipitation of calcium phosphate. The amount lost in this manner is small, and, since cows' milk is at least four times richer in calcium than human milk, the possible loss to the infant is inappreciable. Evaporated milk is as good a source of the inorganic salts essential for human nutrition as pasteurised milk. Vigorous boiling is said to reduce the iodine content by as much as 20 per cent.
